(6) Involved in The Plan are a number of State-Wide campaigns directed specifically at definite causes of needless illness, suffering and unhappiness. These include: A campaign for the control of cancer; continuation of the campaign for the eradication of tuberculosis; a campaign for the conservation of the eyes, prevention of blindness, etc.; a campaign, first, for the control and, later, for the eradication of social diseases; a campaign for the development of mental hygiene—which in words of one syllable means sane living, straight thinking, and the proper control of and education of the mentally deficient; a campaign for the protection of Maine babies, nearly two thousand of whom die each year before they have passed their first birthday; a campaign for the strengthening of local health associations and committees; and a campaign on the importance of proper care of the teeth.

Maine is now widely recognized as the playground of the Nation. With the development of the Health Plan, it is predicted that this state will become renowned as the healthiest state in the union.

The Associated Industries, having had presented to its members the dollars and cents value to them of the health of their workers and its relation to production and industry, are contributing good size checks to the work, contributions which are inspired far more by the spirit of service to humanity than by a selfish interest. Maine manufacturers realize that health is the most potent force that can be marshalled behind any program for the development of a community or state. Money from the annual Seal Sale is being used to a considerable extent. The Granges all over the state are giving box suppers, the proceeds to go for the accomplishment of the health plan. Organized

labor is helping to finance the plan. The Federated Women's Clubs have appointed a committee to devise some way of assisting in the financing of the health program. All of these organizations and individuals feel they helped to originate the health plan. It is *their* "Health Plan" and they do not wish to see it fail.

In most instances local organization is made on a county-wide basis. Each local association contemplates its Medical Advisory Committee composed of local physicians, and its Citizens Committee, composed of representatives from all of the agencies cooperating with the State Association, including the labor unions, industries, clubs, granges, newspapers, ministers, etc. The local affiliated association has its own budget, partly financed by the local share of Christmas seal sale returns, and partly by local memberships, contributions, etc.

When the Executive Committee of the State Granges writes, for example, to the Freeport Grange, suggesting some particular activity in cooperation with the Freeport Public Health Ass'n, the president of the Freeport Grange being one of the Citizen's committee of the Local Health Association, cooperation of the Grange is reasonably assured. Thus are the channels tied to each other.

The most encouraging phase of health work in Maine today is the readiness with which all groups are willing to cooperate in this sort of community activity. Possibly the strongest feature of the Health Plan is the fact that it was organized with the active cooperation and repeated conferences with Maine's leaders in all walks of life. The cooperation in every instance has been thorough and painstaking. It is this cooperation, this concentration on Health matters by the several existing state agencies that is attracting nation-wide comment and congratulations. Maine is the first state in the Nation to attempt a thing of this kind. Letters of congratulations have been received from nearly every state in the Union, from governors, editors, noted physicians, national health authorities from the Surgeon-General of the United States Public Health Service, from the Rockefeller Foundation in Washington, National Congress of Mothers and Parent-Teacher Associations in Washington, from the American Hospital Association, from American Public Health Association, from the American Society for the Control of Cancer, from the National Tuberculosis Association, from United

States Chamber of Commerce at Washington, the American Farm Bureau Federation, the Metropolitan Life Insurance Company, the American Manufacturers Export Association, the Canadian Ass'n for Prevention of Tuberculosis, the American Medical Ass'n. National groups in all lines of endeavor are interested in conserving the health of the American people, realizing that Roosevelt's words were true when he said,—*"To prevent any possible deterioration of the American stock should be a natural ambition."*

Some idea of the way in which the Nation is reacting to the idea of a definite plan of health work on a state-wide scale and promoted by men and women in all walks of life will

Walter D. Thurber, of Augusta, is the executive secretary of the Maine Public Health Association. The Association is pledged, not only to the support of a progressive health program, but to accomplish definite objectives within a given period. Platitudes will not serve; performance is the criterion.

be obtained through the following extracts from a few of the letters received:

R. V. Spencer, executive officer, Massachusetts Tuberculosis League, "I am of the opinion that in making this move you are blazing the trail which every state tuberculosis association in the country must follow."

Dr. C. D. Selby, president of the Ohio Public Health Association, "The Health Plan for Maine has drawn my very favorable attention and I wish to congratulate you upon its splendid accomplishment. The charm of the Plan is in its simplicity; its effectiveness will lie in its power to draw

Maine's influential agencies into harmonious action."

Dr. Eric Crull, president of the Indiana Tuberculosis Association, "I believe you are starting something which is absolutely right. Not only is it bound to be a wonderful thing for the state of Maine but it will drive home to the general public the fact that our fight against tuberculosis is an integral part of the campaign for better health."

Miss Anna Gordon, president of the National Women's Christian Temperance Union, "Surely Maine leads! Day by day she first receives Aurora's light and passes it along. Maine was the first state to send the light of a state-wide prohibition law, now aglow in America and not many years hence it will enlighten the whole world. I rejoice that Maine leads in a state-wide 'Health and Happiness' plan and believe it to be another of her good fashions—bound to be widely adopted."

Dr. Clarence F. Kendall, state commissioner of health, Augusta, Me., "The success of The Plan means more Health and Happiness for the people of Maine. The State Department of Health fully approves of this Health Plan and is working in close cooperation with the Maine Public Health Association in the carrying out of its various divisions."

Surgeon General H. S. Cumming, United States Public Health Service, "While our knowledge of preventive medicine is imperfect and in many diseases we lack essential weapons which are necessary to reduce their ravages, it is nevertheless true that our knowledge of prevention is far in advance of the application of this knowledge by the people. Health officials soon reach the limit of application which can be secured by law and ordinances, and any future significant reduction in morbidity and mortality rates can only be secured by the application of preventive measures by the individual citizen himself. To secure this popular support and especial interest of the individual citizen, it seems to me that your Health Plan will have the greatest value and that it will go far toward securing that ideal condition in which the individual citizen realizes that the prevention of disease is not solely the duty of the health official and frankly recognizes that it is his own obligation."

Dr. A. R. Warner, secretary, American Hospital Association, "the Health of individuals and the average length of life of the citizen of Maine will be improved and lengthened by study and prevention of the conditions that impair health and shorten lives. That past health work has added years to the average length of life is proved beyond dispute and no one believes we have reached the limit. Your program is sound and constructive. Every part has been tested and proved of value."

Joseph H. Defrees, president of the United States Chamber of Commerce, "The Health Plan for Maine is a most encouraging evidence of the way in which Americans are learning to work together for the common good. The purpose and the spirit appeal to me strongly and all the more, per-

The rural districts, too, are to profit by the self-imposed health standards. The Longfellow Rural School, near Ft. Fairfield, Aroostook County, Maine, won the only pennant awarded New England in the recent National Health Tournament of the Modern Health Crusade.

haps, because I am, for a considerable part of the year, a State of Maine man myself."

The Canadian Association for the Prevention of Tuberculosis, "We should have been very proud to think

that your excellent plan for organized volunteer public health effort, should have been undertaken by some part of my Country."

Lucius E. Wilson, president, General Organization Company, "Your

idea of a Health Plan for Maine strikes me as possessing that degree of novelty which is necessary to attract public attention and cooperation and at the same time to be so well articulated as to command the continuing confidence of its supporters."

Dr. James Alexander Miller, president, National Tuberculosis Association, "I am very much interested in your plan for better health in the State of Maine. I think it is becoming more and more evident that as we develop our plans for the prevention of disease and the maintenance of health that it has got to be done by greater cooperation among the organizations and individuals who are interested. I often have felt that our health organizations have kept too much to themselves and have not cooperated sufficiently with other civic bodies and the representatives of business. After all, the health of the community is its most important asset, and not only in dollars and cents but also in comfort and happiness and investment in health is probably more important than any mere business venture. It is therefore with a great deal of interest and sincere best wishes that I shall watch the development of your health plan for Maine and I trust it will have the success that it deserves."

## Cities Go A-Camping

BY MARGARET MOCHRIE, NEW YORK CITY

HE WAS a true child of the pavements—the little boy who, when asked what he thought Heaven was like, replied, "Why, it's a place where you can walk on the grass without bein' chased by a cop." To him, the country was a place to dream of, beautiful and desirable, but very, very far away.

It is rather pathetic, and certainly an unpleasant thing to think about, but it is nevertheless true that there do exist children who have never run in fragrant fields, climbed pasture fences, or "skinned" up a tree. Their natural right to play in the open is often, of necessity, entirely overshadowed by the business of staying where father's job holds them. And that frequently is far from the summer resorts available only to families of considerable means.

Realizing this, and realizing also the vital need for some out-door life, fresh air, good food, and contact with nature in building healthy future citizens, several cities have made it possible, through municipal camps, for their children, and sometimes for whole families, to spend part of the year in the open.

At Fairfield, near Bridgeport, Con-

necticut, there is a country playground which is open from July 15 to September 15. Children may stay there as long as their parents wish, for the very moderate sum of \$3.50 a week. The families of New York City, too, may procure at Pelham Bay Park, only about six miles from the subway, sites 30x60 feet, with a tent 15x35 feet, at the rate of twenty dollars a season. The camp is laid out in streets and is appropriately called "Tent City."

St. Louis, Mo., has given her citizens a "Vacation Village," even nearer the heart of the city than the Pelham camp. In a quiet section of Forest Park, out of sight of autoists and pedestrians, showers and a playground have been installed, and cots and cooking utensils have been furnished by the local Red Cross Chapter. A common kitchen is conducted under the auspices of the Community Kitchen Club. By this means it was possible, during one season, to furnish meals to guests at the rate of 11½ cents per person. The "Village" is used by families from congested quarters of the city, who are recommended by social organizations.

In a little booklet, "Summer Camps,

Municipal and Industrial," issued by Community Service, 315 Fourth Avenue, New York, there are many stories of what cities have done to promote the health of their people

Starting, with tent, blankets, and frying pan, for a week end among the rocks on the New Jersey shore of the Hudson.

through giving opportunities for outdoor life. There are directions, too, for administering various types of camps, and some sample menus and programs of activities.

One of the largest and most beautifully situated vacation spots near New York is the Palisade Interstate Park, a wooded and lake-studded tract of land along the Hudson, developed for the benefit of the children—and the grown people, too—of New York and New Jersey. The Palisades section of the Park lies chiefly in New Jersey and extends along the river for a distance of about twelve miles. It includes nearly all the Palisades river front from Fort Lee to the interstate boundary line. The Bear Mountain and the Harriman unit of the Park lie altogether in New York, along the boundary line of Orange and Rockland counties.

Artificial and natural lakes abound, and everywhere are scenic wonders that rival Switzerland. The roads that skirt the bases of the rock terraces afford marvelous views of the spacious amphitheatres between the mountains. These roads connect the system of Park camps. There are more than fifty of these camps available. Designed primarily to "aid social welfare organizations to bring their charges to the health-giving out-of-doors under most favorable conditions," they are, nevertheless, sometimes used by Boy Scouts, Girl Scouts, and vacation clubs made up of young people whose vacation budget

Ask a boy whether he would rather eat chicken à la King at the best hotel in town or potatoes and frankfurters roasted over a beach fire, and he will choose the latter every time. The beaches at the foot of Palisades are ideal for picnic suppers.

simply won't stretch to cover two weeks at a commercial camp or summer hotel.

The camps, for the most part, accommodate about seventy-five persons. Each one is equipped with a mess-hall and sleeping cabins designed both for proper sanitation and out-door comfort. Special attention has been given to water supply, waste disposal, boat landings, and swimming docks.

The Commission, which administers the whole Park, carries on all construction work, from the building of roads and boats for the lakes, to the erecting of the smallest bath-house. There are no commercial "concessionaires" or any of the "catch-penny" devices with which the ordinary amusement park is infested. Rowing is free, for the first three quarters of an hour, after which a charge of twenty-five cents an hour is made. The Commission manages the candy and soft drinks stands, and conducts a restaurant and cafeteria service at the Bear Mountain Inn for the convenience of tourists. It supplies, without question of profit, transportation to and from camp sites, sleeping cots, blankets, enameled tableware, groceries, milk, bread, and vegetables. And it goes farther than this. It will even deliver to the camps that wish them, cooked meals, piping hot, in vacuum containers.

This last accommodation which the Commission offers to campers is an unique one. It is designed to do away with the waste attendant on buying in small quantities and the ever present and ever annoying cook problem.

Miss Jolliffe, the superintendent of the Camp Department, does not advise camp groups larger than fifty to use the service, as she believes that separate kitchens are more desirable where a great many are concerned. For the small sized

Boy Scouts hike from their camp and cook dinner in the woods around Bear Mountain, woods so dense and wild that one can scarcely believe that civilization is so near.

camp, however, the arrangement is an ideal one.

The food is bought and shipped direct to the large general kitchen. There it is cooked, packed in the heat-retaining vessels—which, by the way, were bought from the government and are of the type used in the army—and sent out in an automobile to be delivered to the various camps.

The price of the meals varies, of course, from year to year. Last season it cost seventy-two cents to feed one person for a day. The food is simple and wholesome, the noon-day dinner usually consisting of meat, potatoes, a vegetable, bread and butter, a plain desert, and tea or coffee. Supper is generally a cold meal—a salad, perhaps—with bread and butter and tea. For breakfast there is a fruit, cereal, bread and butter, and coffee. Sometimes eggs are substituted for the cereal. Where the camps are composed mostly of children, cocoa and milk may be ordered instead of tea and coffee.

The large food service kitchen is run in close cooperation with the kitchen at the Inn. Many a time, when there has been a period of rain, and the Inn has on its hands a supply of food which has been prepared for the transient guest, surprised campers discover that they have been given chicken and pie on Monday!

During the summer of 1921, 91,256 meals were served from the kitchen of the Commission. It is no easy task to deliver, in all kinds of weather, for a radius as far away as seventeen miles, breakfasts, dinners and suppers to hungry boys and girls and men and women. But it was done last year without a hitch, and probably will uphold its record this year, too.

The first delivery takes place at eleven o'clock in the morning—at least, the delivery to the first camp. It is usually about an hour later that the automobile is rid of its full cans of dinner and piled high with the empty containers from the day before. The food will stay hot, if necessary, for twenty-four hours, so the camp director may make the dinner hour at any time he pleases.

The second delivery, at four o'clock in the afternoon brings around supper and the next morning's breakfast. The matron in charge of one camp told the Camp Superintendent that she often took the eggs from the breakfast container, as the children in her care didn't care for a hearty morning meal, and cut them up, hard-boiled, over the supper salad. Some

of the camps added flavoring, and, on special occasions, "frilled up" the vegetables with a fancy sauce or dressing.

The people in charge of the planning of meals try in every way to please their patrons. If a certain camp, for instance, is composed mainly of Jews, beef or lamb is substituted when ham or bacon is on the menu. Sometimes there is a complaint from one camp that too much rice is being served. An attempt is then usually made to give something else to that group when rice is scheduled to appear.

Last year it was reported that there was, in some quarters, dissatisfaction with the large—to them—amount of spaghetti that was being

served. Various groups were asked about it, and there didn't seem to be much opinion one way or the other. It was not until the superintendent visited the children's camp conducted by Greenwich House, that the issue "spaghetti or no spaghetti!" appeared.

"Are we tired of spaghetti!" exclaimed the director there. "Why the children here cry, and say they don't get enough of it! They're mostly Italian, you see." From this one experience it can easily be seen that the diet of the whole system of camps cannot be changed at the request of a few. Some groups, particularly national groups, can stand an infinite amount of one sort of food and still be ready for more of the same thing.

SCHEDULE OF CAMP MEALS

BREAKFAST	LUNCH	DINNER
Monday	Monday	Monday
Stewed Prunes Hot Cereal and Milk Coffee Bread and Butter	Thin Soup Lamb Stew with Vegetables and Potatoes Cabinet Pudding Coffee Bread and Butter	Cream Soup Cheese Sandwich Rice and Tomato Ice Cream Cocoa Bread and Butter
Tuesday	Tuesday	Tuesday
Fresh Fruit Dry Cereal or Milk Toast made of Toasted Rolls Milk Coffee	Thick Soup Corned Beef and Cabbage Boiled Potato Apple Cake Coffee Bread and Butter	Thin Soup Beef Sandwich Noodles Spinach Bread Pudding Cocoa
Wednesday	Wednesday	Wednesday
Stewed Fruit Hot Cereal One Egg for boiling Milk Coffee and Rolls	Thick Soup Hamburger Steak Hash, Brown Potatoes Tomatoes Chocolate Pudding Coffee Bread and Butter	Bologna Sandwich Beet Salad Spaghetti Pound Cake Cocoa Bread and Butter
Thursday	Thursday	Thursday
Fresh Fruit Dry Cereal and Milk Coffee Bread and Butter and Jam	Thick Soup Beef Stew with Potatoes and Vegetables Coffee Bread and Butter Ice Cream	Radishes Frankfurters Potato Salad Boiled Rice Tapioca Pudding Cocoa
Friday	Friday	Friday
Fresh Fruit Hot Cereal One Egg for boiling Coffee Milk Rolls and Butter	Clam Chowder Salmon and Tomatoes Peas Rice Green Salad Pastry Glaced Coffee	Cream of Corn Soup Baked Beans Beets Pie Cocoa Bread and Butter
Saturday	Saturday	Saturday
Fresh Fruit Dry Cereal Milk Bread and Butter with Jam Coffee	Thin Soup Roast Beef Hash, Cream Potatoes Peas Rice Pudding Coffee Bread and Butter	Corned Beef Sandwich Baked Potatoes Rice, Browned Ice Cream and Wine Cake Cocoa
Sunday	Sunday	Sunday
Fresh Fruit Dry Cereal One Egg Milk Coffee Rolls	Thick Soup Radishes Chicken Fricasse Onions Mashed Potatoes Bread and Butter Ice Cream and Coffee	Sliced Cold Meat Cold Slaw Macaroni Cocoanut Pudding Cocoa Bread and Butter

Bear Mountain Inn—Camp Food Service.

CAMP MEAL SUGGESTIONS

We do the best to live up to these suggestions on account of the low price. We must be very careful in measuring out the food. *Don't waste it.*  
The Management.

This municipal camping ground near Oakland, Cal., makes possible a few days or weeks in the woods, at very slight cost.

On the whole, everyone seemed well satisfied with the fare, which really was remarkable for the amount charged for it. Many groups expressed a desire to have the service during the summer of 1922.

Every year, more people are taking advantage of the Palisades as a picnic and camping ground. The nearness to New York, the beauty of scenery, and the freedom from commercialized amusement, all contribute to its appeal to the thousands who want the real country, with woods

and lakes, trees and brooks, and the clear fresh air that comes from the cool, green hills.

For those who desire to plan dietaries for large numbers of vacationers the schedule by menus presented with this article will be helpful.

This menu was the basis of the meals served last year by the Bear Mountain Camp Food Service. The food is remarkably good and it certainly could not be bought elsewhere at the very small sum of twenty-four cents a meal.

## Food From Air a Reality

HOW the exhausted soil of America can be fertilized by means of nitrogen drawn from the air is told by Dr. Robert Calvert, chemist, University of Southern California, in the *New York Times*. Food from the air was the optimistic prediction of a chemist twenty years ago but today it is a reality in Norway, Germany, and at Niagara Falls, Canada.

The United States has obtained its nitrogen supply mainly from Chilean ore, but it is only a question of decades when these fields will have been exhausted. During the war, the government, realizing that nitrogen was the prime ingredient of explosives, built at Muscle Shoals, Alabama, a nitrogen-from-the-air plant. The expenditure, made under emergency conditions, in peace times would have

built a great nitrogen industry which would be a source of prosperity in peace as well as protection in times of war. The plant is now about to be sold, probably to Henry Ford who proposes to utilize the nitrogen to increase the food supply.

America has unlimited resources for obtaining nitrogen from the air. Power from the rivers could be used by day for the usual commercial purposes, and by night, after the busy hours of peak load have passed, for giant electric furnaces for heating the air to temperatures at which the nitrogen will combine with oxygen or other materials for the production of fertilizer.

The water power possibilities of America are of fascinating extent. Niagara, the best known power site, has a drop of 162 feet; the Colorado

River has a drop of 3,000 feet within a flowing distance of fifty miles, with narrow banks which make for economy in dam construction. On the United States' side of Niagara there is developed about 800,000 horse power; one corporation's filings on Colorado River sites total 3,000,000 horse power.

The idea of obtaining nitrogen from air by means of electricity was thought out by Cavendish, an English chemist, who found that the electric spark could be used to combine the nitrogen with the oxygen of the air. For one hundred years the idea lay idle till cheap electric power became available in Norway and Dr. Samuel Eyde supplied financial backing and enthusiasm to take it up. He built five factories from which, as early as 1912, he was shipping nitrates around the Strait of Magellan and selling on the West Coast in competition with nitrate from the West Coast of Chile.

Eyde's is called the arc process. Air is passed through a chimney containing a giant electric arc lamp which heats the passing air to 3,000 degrees Centigrade. One and a half per cent of the nitrogen is combined with the oxygen. The resulting compound is allowed to add more oxygen and is then dissolved in water to give nitric acid. From the nitric acid can be made, if desired, a good nitrate fertilizer, such as lime nitrate. Eyde at Nottodden is supposed to be using some 200,000 horse power. The possibilities at Muscle Shoals are thought to be ten times that amount of power.

The Haber process is the combination of nitrogen with hydrogen. The nitrogen comes from the air, hydrogen from water. Under the influence of heat and pressure and in the presence of an active form of iron, these two gases give ammonia. Ammonia is used as such in icemaking machinery; dissolved in water it is the drug store article of characteristic odor. But for the great uses of agriculture and manufacturing it is converted by oxygen of the air and water to nitric acid.

The American Cyanamid Company has done a great work in developing on this side of the Atlantic the process of combining nitrogen from air with the electric furnace product calcium carbide, which results from the action at very high temperatures of coke on lime. During the war our Government spent millions of dollars at Muscle Shoals in building plants for this process. They were not fully built at the signing of the armistice. Under the terms of the contract with the cyanamid company there was to have been supplied from this plant at Muscle Shoals and from installations of process elsewhere enough of the great high explosive, ammonium nitrate, to correspond to the fixed nitrogen in 500,000 tons of nitrate of soda. Such a project will harness a heretofore unused element of air and make it serve a practical purpose.

# The Popular Bogey of High Blood Pressure\*

**H**EALTH facts are interesting. They would constitute absorbing news for universal consumption if only the general public could keep straight on a few fundamental principles and so maintain the proper perspective. The physician in attempting to discover the details of a particular disease-picture studiously avoids giving undue weight to a single sign, knowing too well that the most distressing symptom and the one which led the patient to seek professional advice is by no means always the most significant in its bearings; that symptoms group themselves into complexes in which primary and secondary manifestations get confused in the patient's estimate of his own condition. Conversely, the patient is chiefly concerned with the most spectacular symptom and is prone to let it worry him out of all proportion to its relative importance. This is particularly true with cardiac instability and the group of organic conditions in which heightened blood pressure is concomitant. Normal psychology in such cases would be greatly favored if it were generally appreciated that high blood pressure is a symptom, not a disease, and it may be a favorable reaction through which is made possible the maintenance of the proper function of the organism. The true status in a given case is not revealed merely by a study of the blood stream either by blood pressure apparatus or by graphic methods of recording the action of the heart, but through the continuous observation of the human machine in action. The importance of heightened blood pressure as a symptom is to be estimated only on the basis of its origin and this is the proper subject for detailed, scientific study. It is better never the object of the patient's concern. Equability—mental and physical balance—plays a highly important rôle in the satisfactory outcome of circulatory disorders. The fear psychoses, so great a menace to the worriers in this group, often constitute the greatest obstacles to proper adjustment.

It has not been many years since the blood pressure machine was introduced into this country, but those years have been filled with concentrated attention to blood pressure such as must astound the thoughtful per-

son who realizes how well the world got along without apparatus for measuring the blood pressure. Today at whist parties one of the favorite subjects of conversation is "blood pressure." People talk about it as if it were a disease, and it has become rather fashionable to be able to say, "Oh, yes, I have blood pressure, too." Most people do not know what they are talking about and were better off without the little knowledge they have. Why, then, has it become so important to have blood pressure taken? What is the significance of fluctuations in blood pressure?

## An Open Question

Speaking from the standpoint of scientific medicine one must admit that at the present time not a great deal is known about the whole subject. The taking of blood pressure by means of the sphygmomanometer has meant the accumulation of a tremendous mass of material, but as yet this material has not been sifted down to a sound basis. Scientific physicians are still working and wondering on many points connected with it.

It may sound silly and yet it seems worth while stating that blood pressure is a normal physiological condition. Everybody whose heart is beating has to have blood pressure to maintain circulation, and what is commonly misconceived as blood pressure is really an increase in this pressure. Perhaps the commonest morbid process associated with increased blood pressure is disease of the kidney—chronic Bright's disease. Because of this association of chronic Bright's disease with high blood pressure, the significance of high blood pressure in other conditions has not been thoroughly appreciated. High blood pressure may occur, probably does occur, without renal disturbance; it is sometimes associated with hardening of the arteries, but not always. It may occur following syphilis, but other infections may be responsible for it. It is probably true that high blood pressure does occur in individuals otherwise normal and without any demonstrable change in the person's body to account for its presence.

What is meant by increased blood pressure is a difficult question to answer, too, because the range of normal blood pressure is not definitely ascertained. Roughly speaking, the popular rule of normal blood pressure

of 100 plus the person's age is accurate enough as a basis, and it must be admitted that many perfectly normal individuals run a blood pressure anywhere from ten to thirty points below the so-called normal for their age without discomfort and without the occurrence of symptoms later in life. Sometimes a low blood pressure is associated with weakened conditions, with anemia, or with chronic disorders. Low blood pressure is said to occur among persons with pulmonary tuberculosis, sometimes with diabetes, and yet it does not indicate the presence of any disease and may be perfectly consistent with normal health.

But how about high blood pressure? What is meant by high blood pressure? As has already been stated, normal blood pressure is a difficult thing to estimate, and what constitutes a high blood pressure for an individual is likewise difficult to understand. One person with a blood pressure of 150 may be in perfect health without symptoms and with a definite tendency not to maintain as good health with a lowered blood pressure. Other individuals with a pressure of 150 may have sudden, sometimes fatal, attacks, involving the arteries of the heart or brain. An individual may undergo a life insurance examination after a fatiguing day's work and be thrown out on account of an increased blood pressure. When in great distress he rushes to his own physician's office, in the course of fifteen or twenty minutes his blood pressure, perhaps starting at a dangerous level will, under the influence of careful examination and reassuring words, drop to within normal bounds. Every physician has seen this sort of a case. A man who had been gambling heavily on the stock exchange was refused life insurance because of high blood pressure. Coming into the physicians office he told a tale of fear that was clearly distressing. The blood pressure machine was kept on his arm and he and the physician sat down for a quiet smoke and talk. By actual measurement inside of fifteen minutes the pressure had dropped twenty-five points and was perfectly normal.

These tremendous variations in pressure occur from day to day and hour to hour, often without any ascertainable reason for the change. With these changes in blood pressure there may or may not be changes in

\*The third of a series of articles on "Popular Medical Misconceptions," beginning with the March issue of THE NATION'S HEALTH.

the individual's condition which would suggest such variations in blood pressure. Many persons in perfect good health run high blood pressure of which they are not aware. Let them become aware of their increased pressure and symptoms are almost sure to arise. The symptoms that do occur are many, but are very likely to be referred to the nervous system. Headache, nervous fatigue, irritability, lassitude, may be complained of and the patient fail to appreciate that there is anything wrong with them. However, individuals with decidedly higher blood pressure may have no symptoms.

The significance of all this must be obvious; namely, that in changes of blood pressure, we have something that is not entirely understood even by those who have devoted considerable time to its study. The folly then of popular notions as to their meaning and value must be apparent. The dangers to the individual are mainly those due to autosuggestion. Unfortunately, today most non-professional individuals immediately associate blood pressure with disease of the kidneys, or with apoplexy, or heart disease. This is well enough, if, on the other hand, these individuals are able to appreciate the fact that in many instances an increased blood

pressure is unquestionably Nature's effort to restore or maintain the function of the body. Practitioners of medicine have all seen patients with what would seem to be a tremendous increase in blood pressure who were in perfectly good health and were able to keep up normal living. As soon, however, as blood pressure was reduced to "normal" such individuals find themselves incapable of carrying on the day's work with the vigor to which they are accustomed.

Common sense is a valuable asset in the discussion and treatment of increased blood pressure. Common sense will dictate whether a patient who has increased blood pressure must be rigidly handled or not. Increased pressure is simply the incidence of a symptom the cause of which must be ascertained and properly treated. The amount of thought and attention which a non-medical person gives to his own case of blood pressure is distinctly harmful to his own condition. The best medical attention is needed and even then not always can the best of advice be given. It is certainly unwise to make the presence of a mere symptom the basis for a course of rigid treatment which may actually confirm a vicious circle and do the individual more harm than good.

placed on screens or racks at the end of long tunnels through which a strong current of dry air is blown. In some systems the food is moved up the tunnel gradually, the temperature becoming higher and the humidity relatively lower, the food arriving at the other end of the tunnel in dry form. In the vacuum system, the food is placed on steel shelves heated either by steam, hot water, or electricity, with a condenser and a vacuum pump to exhaust the air from the chamber and maintain a high vacuum on the system. The vacuum process removes the water, heat is partly by conduction from the metal trays and partly by radiation from the next shelf above.

In the kiln method, square chambers with sloping roofs and perforated floors are utilized. The floor is heated from below by a stove or furnace. The materials to be dehydrated are spread on the floor to a depth of four or six inches. The hot air passes up through the vegetables removing the moisture, and is conducted through the ventilator in the roof. The vegetables are turned over now and then by men with shovels.

The keeping quality of dehydrated foods is illustrated by the fact that at the close of the Boer War a Canadian manufacturer was left with thirty thousand pounds of dehydrated vegetables for which he could find no market. He placed it in barrels which were paraffined and stored away, and at the outbreak of the World War fifteen years later this was shipped to the British army in Europe and used in the preparation of soups of good quality. If kept in paraffined containers free from insects and ingress of moisture, dehydrated food will keep for an indefinite period.

The great advantage of dehydration is that, by and large, it will stabilize the crops of the nation, making food accessible in years of decreased yield.

With an extension of this industry the surplus of years of great yield can be stored and made available in later years when prices are higher and the crop leaner. The amount of planting will be equalized and all will be able to secure an adequate supply of these foods at normal prices.

Dehydration will also conserve food and save the great waste from perishable fruits and vegetables.

The potato dehydration industry, which is comparatively new in the United States, will cause a great saving of hitherto wasted food.

## Dehydration of Foods

THE superiority of dehydration over other methods of preserving food is discussed by Dr. Heber W. Youngken, Philadelphia College of Pharmacy and Science, in *The Scientific Monthly*. In preservation of food by any means it is necessary to keep the enzymes, the chemical agents, and the microorganisms, the biological agents, from spoiling the food. Drying, salting, pickling, smoking, refrigeration, and canning attain this end. Experience has shown, however, that these methods of food preservation often destroy the vitamins, change the palatability of the food, and greatly impair its nutritive value.

Dehydration, on the other hand, preserves the food by removing excess water by means of carefully regulated air currents of properly controlled temperature and humidity, thus preventing growth of enzymes and microorganisms. Food so treated has the advantage of retaining its natural flavor, color, and unimpaired cellular structure. Accordingly, dehydrated food will absorb water and

swell up to its normal size and appearance. When cooked it will have the same appearance, flavor, and odor of freshly cooked material made from fresh vegetables.

Although dehydration dates back to 1850, its methods were not perfected till during the World War when thousands of tons of dehydrated food were shipped to our armies in Europe. Germany probably was able to maintain her food supplies during the war through the dehydration process. Dehydration reduces the weight of the article from 80 to 90 per cent and the bulk is diminished to one-fourth or one-sixth of the original volume. From 7 to 15 per cent of the water is not removed.

The several methods of dehydration now employed vary in detail but are founded on the same basic principle, they remove the water contained in and between the cells of the food so as to obtain a product which cannot spoil as a result of microbial or enzyme action.

In the tunnel system, the food is

# Camps and Beaches in the City of New York

By FRANK J. MONAGHAN, M. D., DEPUTY COMMISSIONER OF HEALTH, NEW YORK CITY

UP TO a few years ago the sojourner from the city to the country during the summer was limited to a vacation season that varied from two to three weeks, with the exception of a small class who could afford the expenditure of time and money necessary to prolong the period. The mountains and the seashore were patronized by thousands of city dwellers, who endured the fare of the country boarding house in order that they could derive the benefits of life in the open and have an opportunity to breathe the pure air of the country for a few weeks.

The ranks of the patrons of the country boarding house are now augmented by thousands of others who establish camps, consisting of tents or bungalows, near a beach within the city limits. The former patron of the boarding house is also found in this newly developed class in large numbers. His limited vacation of previous years he finds can be greatly extended for the same amount of money, since the family meals are prepared as at home and the item of transportation is practically negligible.

## A New Health Problem

The city of New York has encouraged the establishment of these camps by setting aside large tracts of undeveloped park land for their use, and many landholders have profitably entered into the enterprise by renting unoccupied space that was being held awaiting a rise in value.

About sixty-two thousand city dwellers occupied these camps during the summer of 1921. Many other city residents, whose numbers are unknown, also maintained them outside the city limits within short distance from New York.

Their occupancy has created conditions that have been of much concern to the Board of Health, for although the movement has for its primary object the attainment of a higher standard of public health, its attendant consequences, where strict sanitary supervision is lacking, represent a decided move in the opposite direction.

To regulate properly the movement of a large number of people from their substantial city homes, where sanitary appliances are fixed for the disposition of waste matter and for

providing light, ventilation and water, into the flimsy structures in the camps, with incomplete sanitary arrangements and restricted space, is the problem the public health official has to solve.

The large majority of the campers are totally unacquainted with any mode of life, excepting the one they have been leading in the city for years. The resourcefulness of the country dweller gained from experience, to improvise the adjuncts necessary for his comfort and to observe precautions against conditions that are known to be inimical to the health of his family, are faculties that are poorly developed in the average city camp colonist. He only hears a loud and strong call to the primitive life, which conveys pleasant anticipations that produce exhilarating effects, but not even a murmur of the unknown and hidden impediments that mysteriously appear as his journey advances through the new field.

To watch the arrival of a family from the city at one of these camps and their awkward attempts to adjust their living conditions so as to conform to the limited conveniences offered for their use, represents an active and comprehensive visualization of the subject that is of great benefit to the sanitarian who is charged with the guardianship of their physical welfare.

Let us take a trip through the camp with him on his tour of inspection. He first observes the slope of the land and the arrangements for surface drainage, for although the sun is shining brightly now, the time will come when the waters from the clouds above will pour upon the earth and flow along the lines of gravity and least resistance. He pays special attention to the portion of the ground surrounding the dwellings, for the prevention of dampness by means of proper drainage is a question of prime importance with him. Will the water impound is the second consideration, for if it does the ground will be soggy for a long time or possibly the water may lay for a length of time sufficient to allow the breeding of mosquitoes.

He knows in advance that there are no sewers, for this ordinary city convenience is seldom found in a camp. The privy can system will have to be

substituted. The regulations require that these cans be tightly constructed of metal; that they be set upon a base of non-absorbent material with the tops close to the seats and that the base be at least four inches above the surrounding ground; that the seats be provided with tight fitting covers; that an adequate supply of sand or lime be provided in the privy house and that the privy house be adequately ventilated and screened against flies.

When possible, a scavenger service must be maintained. The contents of the cans must be buried deep in a remote place. All garbage and refuse must be kept in tight metal cans provided with tight fitting metal covers, and be removed from the premises daily. Cesspools must be built to receive the discharge of the liquid waste from the kitchens and wash tubs, for city dwellers in the country are prone to throw their liquid waste on the ground. A supply of drinking water drawn from an approved source must be piped to the camp and at least one tap must be provided for every four tents. It is the duty of the Sanitary Inspector to instruct the colonists upon the precautions to be observed in their new method of life, including impressing upon them the necessity of using every possible means of ventilation to provide a constant stream of pure air within the confined quarters they are occupying temporarily and the building of platforms and barriers to dampness.

## Competent Supervision

The camp must be under the supervision of a competent person who will be held responsible for enforcing the regulations of the Board of Health during the absence of the Sanitary Inspector.

The Board of Health has before it as an example, the large number of deaths that occurred in the military camps in this country during the war as a result of influenza. Although typhoid can be prevented through immunization, influenza spreads quickly in quarters that are restricted or improperly ventilated.

We now visit the beach nearby. In addition to the campers, it is also used by a large number of transients from the city. The proximity of the nearest sewer is first ascertained. If a sewer is within five hundred feet the beach cannot be used for bathing

purposes. If over that distance away, the contents of the sewer are colored and the colored liquids observed as they float from the sewer. The colored appearance is retained for a long time, the tests are made under varying tides and if the coloring matter reaches the beach it is a positive indication that the sewage does too. There are certain waters within the confines of the city of New York that are polluted and bathing is not allowed in them under any conditions.

Strong life lines of rope, life belts, surf boats and a competent life guard are required.

The dressing rooms must be substantial and clean and the accommodations for the two sexes must be located in separate parts of the establishment. Sufficient water closet accom-

modation and an adequate supply of drinking water are required for the patrons. Special attention is given to the sterilization of all towels, suits, stockings, and other paraphernalia used by the bathers. They must be sterilized after each use.

In addition to the beaches near camps, there are also many large ones that are patronized by people from hotels or cottages and by transients. They are supervised the same as the other beaches referred to.

The housing shortage in New York accelerates the summer movement toward the beaches. It is a well known fact that has been brought out through investigation that nearly all of the available homes in New York are occupied. The only ones that are not, being those that are held for exhorbi-

tant rents or that are in a bad state of repair. Families have combined in order to secure quarters and all of the tenement buildings contain more people than they did before the war.

For this reason people start for the camps earlier than usual and stay as long as the temperature will permit. Beyond doubt the movement contains much that will benefit the health of those who participate, and as time goes on and the campers gain experience conditions will improve. In the meantime however, the Board of Health exercises unusual vigilance in dealing with the subject of camps, for it is fraught with possibilities that are liable to be more of a menace than a help in promoting the physical welfare of the people of the City of New York.

## The Modern Pay Clinic and the Doctor

BY IAGO GALDSTON, M.D., SECRETARY, INDUSTRIAL SERVICE, NEW YORK TUBERCULOSIS ASSOCIATION,  
NEW YORK CITY

THE opening of a pay clinic by Cornell University, in the city of New York, has once more brought to the fore the matter of popular pay clinics, and once again we are treated to various dissertations by proponents and opponents of the pay clinic scheme. With no aim to contribute to the general confusion and turmoil, what follows is written neither in definite approval nor in condemnation of pay clinics. My specific thesis is simply an economic interpretation of the pay clinic, the forces that bring it into being, and the rôle it plays in the current scheme of things.

It is my conviction that when examined from an immediate social view point the pay clinic proves to be an institution conducive to the improvement of public health and to the prolongation of individual life. It is my conviction, after several years of study and work in and with pay clinics, that the various claims made in their favor are substantially correct and, in the major, warranted. It is true that today only the poor and the rich receive adequate medical attention; the rich from their well retained family physicians and specialists, and the poor through the various charitable organizations, hospitals, and dispensaries. It is true, further, that there is a large middle class, not middle class in the current economic sense of the term, which does not receive adequate medical attention. And finally it is also true

that to some degree the members of this "middle class" do avail themselves of the services of the pay clinics.

Granting all this as substantially true and correct, several pertinent questions present themselves. Is the pay clinic really a solution to the health problem confronting the so-called middle class? If so, to what degree can, and should, the pay clinic, as established today, be extended and perpetuated? And then, too, what are today's relations between the physician and the pay clinic, and what do they promise to be in the future? With these questions set before our minds let us uncover a few facts that must bear heavily upon whatever answers we may see fit to make.

### The Historical Background

Let us first appreciate the development of medicine in the last two hundred fifty years, not from the viewpoint of the various medical discoveries and developments, but rather from consideration of the changes suffered by the science of medicine in its relation to the individuals upon whom it is practiced.

The average physician has but little opportunity for the study of economics or history, and even when he leans toward cultural pursuits he seldom goes beyond the study of pure medical history. The relation, however, of medical history to economics is intimate and profound and an understanding of the same would render

evident many of the causes of the various ethical, social and economic discrepancies between current life and current practice of medicine.

The last two hundred fifty years, have seen one of the most profound revolutionary changes in the entire history of the world. Nothing in previous history can compare with it. No revolution was ever as profound, as effective, as powerful, and as world wide in scope, as the industrial revolution that began in England with the harnessing of steam, and that now has taken root even in China. In the might of that revolution, personified in the three headed monstrous force, steam, steel, and commerce—men and nations were as mere pawns. The face of the earth was changed by its energies; whole races were enslaved and exterminated; the red man was driven from the eastern shores into oblivion; the black man was chained to the yoke of bondage; his earthy virility destroyed by unending toil, strong drink, syphilis, and consumption. The villages and hamlets of old England were razed to the ground to make way for sheep and wool. The old castles of feudalism were abandoned to the sport of time and the elements, and in their stead, arose the strongholds of industrialism with their fiery caves, Stygian smoke stacks, and the perpetual hissing of steam. With all this came corresponding changes in the social relations of men. Nobility and the creed of paternalism were drowned in the

blood of the French Revolution. The force of religious discipline was destroyed by the Reformation. The philosophies of individualism mastered the souls of men,—the philosophies of *"laissez faire,"* of each for himself and the hindmost to the devil. But the hindmost embraced the greater mass of humans—men, women, and children.

Commercialism drove the tiller of the soil from his fields, burned down his hamlet, drove him to the cities, forced him into slums, and then bound him down as an appendage to giants of steel and steam. Commercialism fastened its malignant tentacles not only upon men who were fit for toil, but upon women, too, whether the maid in bloom, or the woman in gestation. Nor did the child escape. The darkest pages of history are not those that chronicle the deeds of Attila and his Huns, but those that describe the bestial horrors of the early factory life. All this transpired in the last two hundred fifty years, and the effects of the ruin, the disruption, and the merciless sacrifice of human life to human greed, linger unto this very day.

With such profound changes in the scheme of human relations, medicine could not possibly escape unaffected, neither medicine as a pure science, nor medicine in its material relation to the lay individual. To the various diseases known and enumerated by Hippocrates and Galen were added those, heretofore unknown sufferings, that sprang from industry, and various noxious elements used in commodity production. The heretofore unknown congestion in the slums contributed to the new health problems; but over and above these came the disrupting effects of the fiendish drive of industry upon the mental and psychic fabric of man. In the narrower sense these were technical problems; problems that lent themselves to solution by the genius of individual men, and with the passing of time many of these technical problems were solved. But the greatest problem of all, the problem of the readjustment of relations between the medical practitioner and the economically disfranchised mass of toilers, has not yet been solved; in fact, but few practitioners are intelligently and understandingly conscious of the existence of the problem and its nature.

The pay clinic is a feeble attempt at the solution of one phase of this pressing problem, the phase of inadequate medical attention available to

the average toiler. It requires but little thought to discover that this problem is essentially an economic one. Why is it that the large mass of individuals is without adequate medical attention? Is it because they do not need it, or do not want it, or that there are insufficient physicians? Hardly! It is because, as organized at present, these self-respecting men and women are caught between the two difficulties of self-respect and economic limitation. They will not go to the dispensaries; they cannot, without much privation consult a private practitioner. In the same vise too, is caught the medical practitioner. He is no less liable to the economic forces of current society than are the rest of the cogs of the great industrial machine-society of today. If he would live, the "cash nexus" must be the basis of his practice.

And so, as a solution, comes the pay clinic, with its cheap fees and its mass service. As a palliative, one may grant its effectiveness; as a cure, one must doubt.

### The Personal Equation

Medicine is spoken of as a science. It is a science and in the finest sense too, but medicine is also an art. One cannot practice medicine as one practices architecture or engineering. There are laws in medicine that are as basic and positive as the laws of architecture and engineering, but it is in the manipulation of these laws that the art element of medicine is inherent. No case is identical with any other case, nor will any solution in the one circumstance precisely fit another. Even the causes of the same condition will vary from time to time. Mass service in medicine makes use of the science of medicine, never the art. I can conceive of no circumstances under which medicine can be practiced satisfactorily in which the personal relation of the physician to the patient is not thorough and complete. When the patient is merely No. 1 or No. 7 in the clinic series, as he is in the service of the pay clinics, medical practice is but a make shift. This is especially evident in the light of what is common knowledge to all practitioners, to-wit, that among the forces operating to bring the patient into the office of the physician, the mental element of his sufferings is the strongest. One of the most common complaints heard against the pay clinic comes from patients denied the opportunity of airing and circumlocuting their difficulties. And the majority of these patients suffer more from

precisely this lack of opportunity to air their difficulties than from the physical discomforts of the difficulties themselves.

Upon this theme we may be permitted to project our thoughts into the space of future time, and to conceive that the character of the relations between physician and patient must, of necessity, become more personal and intimate. Thanks to the various schools of psychotherapy, Freudian or otherwise, the average physician is now impressed with the importance of taking the psychic status of the patient into consideration when according him treatment. The mere writing of a prescription and the assurance "all will be well if you take these pills three times a day with plenty of water" no longer suffices, in the majority of cases. Nor can it either! Life has become too complicated, and adjustments too difficult, for the average individual. And the doctor, with his knowledge of the structure and function of the human body, is called upon to help in making the necessary adjustments and to point out the "rational way," as did the priest in former times. Further, too, the element of prevention in medicine is beginning to dominate the element of treatment, and in the former, in contrast to the latter, education plays an extremely important part. Treatment is essentially a function of the physician, whereas prevention implies the understanding co-operation of the patient. To develop such an understanding cooperation, however, education is necessary, and in time the physician in his relations to the patient will be essentially an educator. This is, of course, as it should be and, when we have reached this stage, the practice of medicine will have attained a truly high development.

All the foregoing precludes the possibility of mass treatment and presupposes to the contrary the most intimate relations between patient and physician. It further implies an economic condition in which the "cash nexus" basis in the relation between physician and patient has been displaced by one in which the economic interests of the physician are sufficiently well taken care of, and all of his energies liberated, for the sufficiently trying task of the competent practice of medicine. This is not provided for by the pay clinic, nor even by social health insurance. Both these schemes are palliative and, to that degree, are of some benefit to man. But, as physicians who are es-

essentially interested in cures it behooves us to look elsewhere for a competent remedy. We must look for it in a change in the economic relations between men, in a higher social sense of obligation, in the death of the "cash nexus," and in the substitution therefor of a real humanism.

The chief virtue, therefore, of the

pay clinic of today is that it is a fairly competent palliative, but if we are allowed to speculate on its future, it appears that some day it will come into its own. The individual relation of physician to patient must be retained, but undeniably the gross technique of medicine requires far more equipment than the average physician either can or should possess. While,

therefore, the physician should continue to play the rôle of a sort of father confessor and chief guardian of the individual's psychic and physical soundness, he should at the same time also have at his command, and make use of, the various instruments and experts available. And to this end the now organized pay clinics may in due time be made to serve.

## Recreation Association Makes Reports

**N**EARLY nine million dollars was spent for purposes of recreation by 458 cities in the last year, reports the Playground and Recreation Association in the March issue of *The Playground*, fifty-three cities having donated playgrounds, and eighteen of the number placing the value of the property so delegated at \$1,182,700.

Five hundred and two cities report 4,584 centers under paid leadership, the largest number recorded. Workers to the number of 11,079 were employed to direct play at these centers. Municipal funds were used for the entire support of the work in 244 of the cities. Reports from 1,170 cities bring out the generally awakened interest in recreational activities.

The fact that 502 cities report playgrounds and recreation centers maintained under paid leadership during the last year is considered most encouraging by the Association, representing as it does a satisfactory increase over 1920, when 465 cities so reported. The total of 4,584 centers also shows satisfactory growth, as compared with the 4,293 reported last year.

In addition to the 502 cities which are carrying on recreational activities under paid leadership, centers are maintained in many other cities, as shown by the reports received. Among these are school playgrounds in 101 cities, school playgrounds with special paid leaders in three cities, centers under volunteer leadership in six cities and unsupervised centers in fifty-nine cities.

Fifty-one cities initiated the work during 1921, thirty-four of them wholly or partly under municipal control. In addition, twenty cities report ground and equipment purchased with a view to establishing the work, and twenty-two cities suggest definite plans for work next season.

Of the 502 cities listed in the statistical table of the report, sixty-eight show 147 centers used exclusively

by colored children. Some of the cities report playgrounds used by both colored and white children.

A steady increase in the number of employed leaders is a feature of the work. This year's total, 11,079, exceeds the 1920 report by 861. Of the number, 5,181 were men and 5,898 women.

As the number of trained workers in this field is growing steadily, training classes for them, whether employed or volunteer, are being established in a growing number of cities. There were ninety-four cities conducting such training classes in 1921, with an enrollment in fifty of these cities of 1,580. Training classes for volunteer workers were conducted in sixty-nine cities, as compared with nine in 1920, and thirty-five of them reported an enrollment of 1,890 students. A marked improvement is shown in the number of cities requiring civil service examinations for recreation positions in 1921, this being forty-one, as against twenty-six in 1920.

Various forms of municipal administration are reported by the 367 cities, the playground work of which is supported in whole or part by municipal funds, the managing authority being the School Board in 128 of the cities, while in eighty-eight of them power is vested in Playground and Recreation Commissions or Departments, Division Boards and Bureaus of Recreation. In fifty-six cities the work is under the authority of Park Boards, Departments and Bureaus or Park and Recreation Commissions.

In the balance of the 367 cities almost every civic organization extant has apparently been called into service to manage and control the recreation work, including Departments of Public Welfare, Departments of Parks and Public Property, City Councils, Boards of Trustees or Selectment and Departments or Boards of Public Works. In one town the local Public Safety Committee was called upon; in another the Department of Streets

and Public Improvements; in another the City Planning Commission, while in various other cities and towns the City Health Department, the Department of Public Affairs, the Public Recreation and Welfare Commission, Municipal League and the Public Athletic League of the county were called upon to handle the work.

In almost 200 cities the managing authority was vested in private organizations, these having the widest possible range, from the Red Cross to the Rotary Club, and covering churches, industrial plants, women's clubs, the Y. W. C. A., the Y. M. C. A., various boys' organizations, parent-teacher associations, settlements, and even, in some cases, private individuals, the last being the case in seven cities. In other cities private organizations and municipal departments combined in the management of the playgrounds and recreation centers.

More than five million dollars voted in bonds for recreation purposes is the report from twenty cities. This figure includes Duluth, Minn., with fifty thousand dollars voted for a municipal golf course, and Akron, Ohio, which made two million dollars available for establishing parks and playgrounds. Memphis, Tenn., plans to spend one hundred thousand dollars on a municipal swimming pool.

A total average daily attendance of 1,154,983 is reported by 407 cities. For attendance at Winter centers, 585,761 is reported by 158 cities. A growing use of playground facilities during the evening hours is noted from year to year. Other features of the report are the closing of streets for play, where city authorities safeguard the lives of thousands of children who lack playground privileges.

The number of cities reporting play streets thus established during the year is thirty-eight, twenty-five of them providing play leaders. Ninety-eight cities report safeguarding streets in Winter for coasting.

# The Sheppard-Towner Bill

By EMELIE M. PERKINS, SUPERVISING NURSE, BURLINGTON VISITING NURSE ASSOCIATION, BURLINGTON, VT.

SO MUCH has been written and spoken regarding the Sheppard-Towner Bill that it would seem as if there could be nothing further to add. But, although the bill has been passed, it is still possible for the states individually to refuse the grant of money from the Federal Government and, since that is possible, the matter is still open. A short time ago, at a conference of doctors, this question was brought up. The Medical Association of the state had gone on record as being opposed to the passage of the bill, and it appeared at the conference that the feeling was unanimously against the bill, but when the doctors were asked to indicate by a show of hands how many had read the bill, less than half of them responded in the affirmative! Under these circumstances, it is not surprising that clear and logical reasons for opposing the bill are hard to find. Even among these physicians—educated men—there were some who believed still that the bill would bring in compulsory registration of pregnancy! And this in a body of men who would laugh at a woman for believing that she could wean her baby only at the full of the moon, because a neighbor had told her so!

Paternalism was the bogey man for most of them. The fear of pauperizing the free American people, was another argument advanced. Also, the fact that state plans must be submitted to Washington for approval, influenced some. Because so much publicity has been given to the side opposed to the Sheppard-Towner bill, and because literature describing the degradation of the American people under the bill, is so much more available and so much more startling than the arguments for the bill, it seems only fair that more efforts should be made to explain the provisions and the desired results, as seen by adherents of the bill.

The first fact which confronts us is that the United States is seventeenth—the last—in the list of countries which keep statistics regarding the death rate of women during childbirth, or from causes due to childbirth. That is, that in the United States, out of 1,000 women giving birth, more will die than in any one of the other sixteen countries which keep statistics on this subject,—certainly not a fact in which we can

take pride! Furthermore, we are doing little to lower this death rate. Comparatively few cities have provided prenatal and postnatal care for the mother, and the number reached is very small. That seems to me the answer to those who would place this work under state control. They have not established prenatal care, education in the hygiene of pregnancy and infancy, medical care at time of delivery, nor postnatal care. They do not now propose any definite plan whereby this work can be carried on by the state, and if it were left to the initiative of the individual states, some would surely neglect it, and the death rate would not be materially lowered. While we argue about it in this fashion, with no constructive suggestions, we hear continually of mothers lost through eclampsia or septicemia, both so often preventable.

In regard to pauperizing the people, a question also raised by the medical profession in regard to clinics, it seems that we who announce loudly that we cannot support a family on less than fifteen to eighteen hundred dollars a year, should realize that food and clothing and fuel cost the laboring man just as much as they cost us. The man who earns \$2.40 a day, supports a family of five, pays hospital and physicians' bills for a sick son, must necessarily go without something absolutely essential to mere health and well-being. And if in addition he must save for his wife's confinement and aftercare, the problem becomes a very serious one. As a matter of fact, women have shown themselves unwilling to accept free care during confinement, when they could possibly pay for that care.

And how many college students pay the entire cost of their education? They do not even pay in proportion to their means, for some of them are driving their own cars while they are accepting the bounty of the state, or of the private individuals who have endowed their particular colleges, but no one worries about pauperizing them. Some of them, of course, will make contributions to science or industry, and these will repay for all. But surely, the mothers saved by the care provided for in the Sheppard-Towner bill, would repay, too.

As far as paternalism is concerned, why is that such an alarming word? Compulsory education is surely pa-

ternalistic, but no one complains of that. Paternalistic seems to mean the provision of any measure by the central government at Washington. We elect the President as surely as we elect the Governor, so why need we oppose a measure simply because the central government reserves the right to approve the states' plans?

The need for such measures as are provided for by the Sheppard-Towner bill, is not even considered by the opponents of the bill. The most telling of all arguments "and meanwhile, the women die," is waved airily aside. One opponent of the bill has stated that practically every village and hamlet in the United States has its physicians and nurses. Dr. Nicholl, Deputy Commissioner of Health of New York, at the last meeting of the State Medical Society, said that in the last two and one-half years, eighty-six communities in New York state alone have appealed to the State Commissioner of Health to supply them with physicians. Thirty-two are still without physicians. And it is not only in these districts without physicians that the need is felt. The other day a woman died of septicemia, following childbirth. This happened in a city well supplied with physicians. The factor in this case was ignorance. The woman was delivered without a physician, and had no aftercare, either medical or nursing, for several days. The bill provides explicitly for education in the hygiene of maternity and infancy.

It is easier and pleasanter to repeat our neighbors' opinions based on the opinions of a neighbor of *his*, than it is to inform ourselves accurately, but it is a grave responsibility to nullify, either through personal economic considerations, or through laziness, a measure which can prevent deaths. Any really vital defect in the law will be brought out by measuring its provisions against the actual situation in the field it is designed to cover. The prompt acceptance of the measure by thirty-six states indicates that it actually does meet local needs and gives promise of early determination as to the adequacy of the measure. In the meantime, let us inform ourselves concerning the exact provisions of the bill, and also concerning conditions in our own communities, and then—and not till then—let us express an opinion.

## Jules Schevitz, 1897-1922

By MURRAY P. HORWOOD, PH.D., DEPARTMENT OF BIOLOGY AND PUBLIC HEALTH, MASSACHUSETTS INSTITUTE OF TECHNOLOGY, BOSTON, MASS.

WHEN night falls at the end of a long, and beautiful day, its enfolding, comforting charms are welcome indeed. But when darkness comes shortly after the the dawn, black night loses its comforts and repose. The problem of life has always been linked up with the problem of death. The postponement of premature death has been the goal of the public health and medical professions. It is therefore distressing beyond description, when a young, promising life, in the development of its fullest strength, power and beauty is taken before it has had time to flower.

Such is the story of Jules Schevitz, recent general secretary of the Oklahoma Public Health Association. Mr. Schevitz died on March 22, 1922, at the age of 24, only at the dawn of a promising career of attainment and service. Even at his early age, he had attained a degree of prominence and accomplishment, usually achieved only by men of maturer years.

Jules Schevitz was born in Brooklyn, N. Y., on June 1, 1897. Educated in the public schools of that city, he rapidly made his way to Townsend Harris Hall and later to the College of the City of New York, from which he received the degree, Bachelor of Science in 1917. At the end of his junior year in college, he developed pulmonary tuberculosis and through the active interest of his friends, and especially of Professor C.-E. A. Winslow, he was able to spend a year at Trudeau, N. Y. There he had the good fortune of coming under the spell of Dr. Edward Livingston Trudeau, the pioneer in sanatorium treatment of tuberculosis in the United States. Many other maturer men, afflicted with the same disease, helped to mold his mind and his career and from these he received the inspiration for his life's work.

At the end of one year, he returned to New York City, robust in health, and mature in thought. He resumed his studies at the College of the City of New York, specializing in the biological sciences, and particularly in public health. His schedule being light, he undertook a public health survey of Union Hill, N. J., which he conducted in a highly efficient and satisfactory manner. In June, 1917, he attended Dr. Jacob's

Tuberculosis Institute in New York City, from which he derived immeasurable stimulus and satisfaction. During the summer, he conducted a Tuberculosis Survey of the State of New Jersey, which immediately demonstrated his ability, his thoroughness, and his keen love for the work.

In September, 1917, at the age of 20, he was appointed Secretary of the Oklahoma Tuberculosis Association. Little had been done in the organization and conduct of the Anti-Tuberculosis work in Oklahoma, and almost single handed, Mr. Schevitz had to begin to build the splendid monument to tuberculosis and public health work which he left behind. Plunged into

Jules Schevitz, general secretary to the Oklahoma Public Health Association and member of the Editorial Board of THE NATION'S HEALTH, died in Oklahoma City on March 22, 1922.

the seal sale campaign immediately after his arrival in Oklahoma, he was able to raise more than forty thousand dollars, an increase of 2000 per cent over the amount raised the preceding year. The splendid showing of the seal sale insured an extensive and progressive public health and tuberculosis campaign during the coming year.

There followed in rapid order, the organization and development of the program of the Association. A splendid, active, and interested Executive Committee for the State Association was appointed, and similar committees were found to serve first in the larger municipalities and then in the more

rural parts of the state. Trained tuberculosis and public health nurses were carefully selected from all parts of the United States. Tuberculosis clinics were established and placed under competent medical supervision, infant and child welfare work was initiated and conducted, and similarly, school nursing activities were begun and fostered all over the State. Special attention was given to the introduction of public health activities among the Indians and Negroes, and to the care of discharged tuberculosis soldiers.

Realizing the need of improving the general public health situation in Oklahoma, as a means of combating tuberculosis, Mr. Schevitz instituted a series of public health surveys in the larger cities in Oklahoma, thus conducting what constituted the first thorough, state-wide public health survey of urban conditions in an American state. Public Health nursing institutes were held from time to time, exhibits were planned and erected, special pamphlets on tuberculosis, infant and child welfare and on the communicable diseases were printed and widely distributed. Other methods used in the campaign of public health education, and particularly the medium of the newspaper, were employed. Mr. Schevitz also edited a popular monthly bulletin, which contained all the news of the activities of the Association. In addition, he also served as a member of the editorial board of the NATION'S HEALTH.

Realizing the need of adequate hospital facilities for the care of the tuberculous in Oklahoma, Mr. Schevitz waged a legislative campaign for sanatoriums, and succeeded in getting the legislature to pass a bill providing for the construction and maintenance of three sanatoriums, two for whites and one for the colored tuberculous at Clinton, Talihina and Boley, Okla. The provisions of this bill were so well drawn that Mr. Schevitz received the admiration and commendation of prominent tuberculosis members all over the country.

This account of the activities and attainments of Mr. Schevitz, though incomplete, speaks very highly of his fruitful, young life. As a worker he was indefatigable, and there was no limit to his aspirations for the improvement of the public health of

Oklahoma. In the brief span of four years and six months, he had placed Oklahoma in the forefront of public health progress, and made her name known abroad as well as at home.

But it is the remarkable conduct of his life, that is perhaps the most abiding and cherished memory to those who knew and loved him most. Activated by a high ideal of service to his fellow-men, he gave of himself without stint or limit to the cause of public health. His motives were always transparent, and his charming and pleasing manner, combined with

a graciousness of spirit, made his path among men and women easy. His was the affectionate nature, and the splendid state-wide organization which he has left as a monument to himself, is cemented by the love and devotion of those with whom he was associated. He was kindly in his relations, courteous to the extreme, and a gentleman on all occasions. He was extremely tolerant of the shortcomings of others and sensitive to their pains and sufferings. He craved the affection and good will of all who knew him, and by his behavior he

rarely, if ever, failed to obtain it.

He loved Oklahoma. To him it was a land of rare opportunity. He saw its tremendous possibilities and strived as hard as he knew how to make his particular contribution to its development. He came to give to Oklahoma, and in so doing he was amply rewarded. His was the durable conquest, one that will linger in the minds of men for many years, and in the work of the Oklahoma Public Health Association, as long as it endures. The country has lost a brilliant health executive.

## Digest of Sanitary and Hygienic Advance

IT IS not necessarily in the isolated case of outstanding interest nor in discoveries of new and rare conditions that health officers are chiefly concerned, but in new light on old problems and in possibilities of prevention growing out of newer practice. Especially is it necessary and desirable to follow what their confreres are doing.

**Purgatives and Health.**—The Health Officer who would keep his clientele in good physical condition will find a fertile field of labor in combating self-purgation. Mankind's predilection for taking things out of a bottle may perhaps be explained in part by the widespread prevalence of constipation, induced to a very large extent by man's artificial diet. At any rate, the amount of laxatives, purges, and salines consumed annually by the general public is enormous. The particular drug used varies considerably according to local preferences, but the great fact is that there is altogether too great a prevalence of purge-taking. In certain sections calomel and soda is taken "to turn over the liver," in others, magnesium sulphate and the various effervescent salines are the mode; while many prefer the combinations of aloin, senna, cascara sagrada and the other vegetable compounds to "start the bile." Aside from the actual harm done to the digestive tract by the constant derangement produced by irritant drugs, there is the danger of poisoning by calomel taken to relieve constipation caused by unrecognized bowel paralysis, ileus, or incarceration and every surgeon has seen appendicitis fatalities resulting from the stimulation of an intestine which Nature was trying to keep at rest. The habitual use of concentrated foods, the drinking of too little water, the

easy chair and the slothfulness which accompanies it, these are the arch-producers of chronic constipation. The cure or improvement of the condition is largely a matter of the regulation of the habits of daily life and is not to be effected by the miscellaneous ingestion of drugs of any sort. Constipation may be a serious condition, but in any event self-purgation is not the remedy.

**Education of the Appetite.**—It is true that many people live to eat, also that they are the ones who dig their graves with their teeth and who thus furnish the residuum of unexplained premature deaths which health officers are now laboring to reduce. It is not entirely the simple matter of over-eating or under-eating so far as gross quantity is concerned, the amounts and proportions of the food accessories also play a very great rôle. This latter phase of the subject is receiving very considerable attention at present and the problem in its various phases is being subjected to intense study in many parts of the world and under widely diverse conditions. As a result, very considerable additions are being made to the knowledge of human metabolism and it has already been possible to apply these facts in a practical way. To a certain extent, the health officer can do much toward the control of the deficiency diseases through educational methods, but it should be remembered that the education of the adult appetite, as Mr. Volstead can testify, is very difficult of accomplishment. To educate an appetite it should be caught young, not much later than the grammar school period, and carefully instructed for a long time. Parents will take far more kindly to the control of the child's appetite than their own. Therefore,

the most lasting results may be obtained by teaching the child what and how much to eat, while the parent is instructed in the importance to the child of a well balanced and adequate, but not excessive, diet.

**Malaria Relapses.**—One of the most disappointing things in anti-malaria work is the frequency with which relapses occur, particularly in persons of subnormal vitality. This sometimes constitutes an economic loss of considerable magnitude. Recurrences and relapses as a rule result from incomplete treatment, the added factors being fatigue from overwork or exposure and concomitant helminthiasis. The latter factor is one which is frequently overlooked and the search for intestinal parasites and the treatment of the condition should be instituted as soon as the temperature has reached normal. This should be a routine part of malaria treatment.

**Sputum Commerce.**—Comparative plotted curves of the mortality rates from the fecal-borne and the acute, sputum-borne infections for the past quarter century will show that, whereas there has been a continuous fall in the former, the latter has risen at an even greater rate. This of course means that there has been an increasing opportunity for sputum interchange between the sick and the well. The most obvious phase of the problem has been attacked by the "Do-not-spit-on-the-floor-to-do-so-may-spread-disease" campaign, a movement of the utmost value from the educational view-point and one which has undoubtedly done much to teach the potential dangers of promiscuous expectoration and to control a very widespread and disgusting habit. The changing habits of community life since the time when the bulk of the population ate in their own homes and

when the average individual traveled comparatively little are probably responsible to a considerable extent for the increase in the acute sputum-borne diseases. More people eat in public places nowadays than ever before and modern transportation tends to increase the amount of restaurant and hotel life. Unless the mess-gear used in these places is sterilized between usings, the opportunities for its serving as a vector for the organisms of disease is markedly increased. This is to a certain extent offset by the popularization of the automatic dishwashing machine but in places like the soda-water fountain and the similar soft-drink emporiums which have replaced the saloon, it is extremely difficult to secure efficient cleansing and sterilization of glass-ware. Disinfection by heat is objected to because of the heavy losses from breakage and also because of the slowness with which cooling occurs, a serious fault from the view-point of the iced-drink vendor. It is believed that mechanical sterilization in cold chemical solutions is practical. To be sure the washing machine would have to be resistant to the chemicals to be used but there are now on the market metals which could be used very effectively for this purpose. Efficient rinsing after sterilization would be also necessary. The entire question is worthy of careful study at the hands of practicing sanitarians, for certainly the control of the sputum-borne infections is one of the most serious problems which now confronts them.

**Carbon Tetrachlorid as an Anthelmintic.**—Researches which have been recently made by M. C. Hall, Senior Zoologist of the U. S. Bureau of Animal Industry, indicate the practical utility of carbon tetrachlorid in the treatment of helminthiasis and at about one-eighth the cost of the methods previously used. The well known disadvantages of thymol, its cost, occasional toxicity, and the necessarily elaborate preparation of the patient have led to an endeavor to discover some more practical drug. *Chenopodium* has been used with good results, but Hall's reports indicate that carbon tetrachlorid in doses of 0.3c.c. per kilo of live weight is an anthelmintic of great potency when used on dogs. He reports that when administered in hard gelatin capsules after an eighteen hour fast and without previous purgation, it is equally efficacious in removing *Ascarides* and *Strongylus* from horses and swine. In a series of therapeutic

tests on Fiji coolies, he is reported to have been able to remove 98 per cent of the hookworms with a single dose of carbon tetrachlorid without untoward symptoms. It is highly probable that the dosage for human beings is considerably less than that to be employed on animals.

**Prevention of Measles.**—Years ago Munson in his "Military Hygiene" reported his observations in the prevention of measles by the injection of serum removed from the blisters artificially induced on convalescents. Curiously enough, this work has been lost sight of, probably because Munson did not carry it further. Degkwitz in a recent issue of *Bulletin et memoires de la societe medicale des hopitaux de Paris*, has stated that as small a quantity as 3c.c. of serum from recent convalescents will prevent the development of the disease. He further states that injections done up to and including the sixth day after exposure will protect, but after the seventh day such injections neither prevent nor modify the disease. Doses smaller than 3c.cm. injected before the seventh day after exposure lengthen the period of incubation, shorten the course of the disease, and prevent secondary complications. This work merits confirmation and further extension.

**Bacteriological Diagnosis of Mild Plague.**—The difficulty in diagnosing ambulatory or very light cases of bubonic plague is sometimes a considerable handicap to the sanitarian. It has been recognized for a number of years that Yersin's bacillus is present in the blood stream very early in the disease in practically all cases and it may be recovered and recognized by appropriate blood cultural methods. This is of great importance, since the punctured bubo does not always yield bacteria and a negative result does not by any means indicate that the case is not one of plague. While a missed case is not as grave a matter in a plague epidemic as it might be in a typhoid outbreak, it is a serious fault since all human foci should be discovered in order that eradication operations may be accurately directed. A practical method of diagnosis consists in making a blood culture. If a good sized sample of blood (50 to 100 c.c.) is taken from the patient under aseptic precautions, planted in one and one-half times its volume of peptone bouillon, incubated at 25 degrees centigrade, and the usual technic of determining the plague bacillus carried out, cases which otherwise would pass undiagnosed will be discovered.

**The Amelioration of the Deaf.**—The health officer who views his profession with broad-angle vision realizes that the perimeter of his operations does not simply circumscribe the infectious diseases, the correction of nuisances, the control of foods, and the collection of vital statistics. His work includes as well every phase of human existence and every circumstance of mind and body which lower human efficiency and longevity. Thus everything in human life from the prenatal stage to old should pass within his purview.

From this conception of the wide scope of his functions, the amelioration of the condition of the deaf or partially deaf becomes a part of his duties. Such persons are an economic hazard to the community and their lot is frequently very sad indeed. The organization of the hard-of-hearing into leagues for mutual aid has met with considerable success in several large cities. The purpose of such organizations is the inauguration of classes in lip reading, the formation of social clubs, and employment assistance. Such leagues are not only of tremendous benefit to the unfortunates by their education, they also form a social outlet for a group whose infirmity to a certain extent enclosters them. To the health officer they are a valuable aid, and should therefore be encouraged.

**The Mechanism of "Catching Cold."**—It is a widespread observation of long standing that chilling and wetting of the body produces a series of physical changes ranging from a mild coryza to a severe pneumonia, but the scientific proof of the mechanism by which this occurs has until recently been lacking. It is now known, according to Mudd, Grant and Goldman, in the March, 1921, issue of the *Annals of Otology, Rhinology, and Laryngology*, that many of the potentially pathogenic bacteria lead a saprophytic existence on the mucous membranes of the upper air passages and that under appropriate conditions they produce an active infection of the body. The chilling of the body surface causes a reflex vaso-constriction and a resultant ischemia of the mucous membranes in which these organisms may be resident, thus lowering the activity of the protective properties of the lining membranes of the nose, palate, tonsils, and pharynx and establishing a portal of entry for bacteria. Conversely, the air of hot, dry crowded rooms causes an engorgement of these membranes and favors coughing and sneezing, the acts by which the infectious material may

be spread from person to person. A subsequent chilling constricts the surface blood vessels of the swollen membranes and hence favors infection.

There is no more important phase of health officer's work than in educating his clientele in the means of preventing colds, since they are so frequently the precursors of serious infections and hence are such a great economic hazard to the community.

Recognizing the mechanism of "catching cold," makes it relatively easy to formulate the advice to be given to that end, yet care should be observed lest an unwarranted fear of draughts and exposure be induced and it should be borne in mind that a regimen of life suitable for the robust might be very harmful to puny individuals. Out-of-doors life and the following of a sane sanitary existence are to be

insisted upon, as are also good ventilation, the avoidance of over-crowding, and the proper treatment of any ailment or abnormality of the upper air-passages. The overheated house, the dusty public conveyance, the irritating smoking room, and the "dead-air" theater are to be shunned. Exercise and cold bathing in proportion to individual physical fitness are to be recommended.

## Problems in the Bovine Tuberculosis Question

### The Metamorphosis of Types Offers an Interesting Field for Investigation

By J. HOWARD BEARD, UNIVERSITY HEALTH OFFICER, UNIVERSITY OF ILLINOIS, URBANA, ILL.

**A**MONG bacteria is found a group of bacilli whose strains are characterized by their like ability to retain the dye when stained with carbolfuchsin and subsequently treated with dilute mineral acids. They differ, but their difference is more quantitative than qualitative. Animals, sensitized to one strain, exhibit partial immunological reactions to the other types, indicating that, chemically, at least, the cell structure of the organisms of the various forms are similar.

The great majority of the "acid-fasts" are saprophytes, but certain strains, of which the human, bovine, and avian tubercle bacilli are the most distinguished representatives, are parasitic. Others are harmless, but may acquire pathogenicity. For example, *B. subtilis* is usually a saprophyte, but it may become a secondary invader of wounds or give rise spontaneously to inflammation of the eye.

A form of "acid-fast" organism causes disease in the blindworm. Fish, particularly carp, may become infected by a member of this group, which is also able to kill frogs. It also produces tubercles in snakes, lizards, and turtles. The pathogens of the "acid-proof" organism attack most frequently and most vigorously warm-blooded animals in captivity or those that are housed. Their strains produce specific chronic enteritis and tuberculosis in cattle. Their types cause leprosy in both man and rat. They produce phthisis in man, beast, and bird.

Whether or not all the strains of this great class of bacteria have a common ancestor and are modifications of the same organisms produced by environment, offers an interesting

*Tuberculosis is not a provincial problem of a species, but a world wide one, co-extensive with the animal kingdom. The veterinarian, in his study of the disease, must run the biological scale from the lowly blindworm to the anthropoid ape. The physician, in his endeavor to comprehend the "acid-fasts," must descend the ladder of animal life even unto the lizard. He and the veterinarian will meet at many points to join hands in search of the secrets of Nature essential to the prevention of the great economic loss and to the limitation of suffering in man and in beast from tuberculosis.*

field for speculation. Whether or not one virulent type may be transformed into another awaits a conclusive demonstration. Certain investigators have asserted their ability to transform mammalian strains into the cold-blooded types by passage through blindworms or through frogs. They also claim to have changed the bacillus of fish tuberculosis by culture and by injection into animals until it has become highly virulent for mammals. Many observers believe certain saprophytic "acid-fasts" may be trained to parasitism and develop ability to cause local lesions, but not to produce generalized tuberculosis.

In trying to convert types, the human and avian forms have been passed through many cows; the human and bovine through many chickens. Nocard placed a culture of the human type in a collodion sack and

introduced it into the abdominal cavity of a chicken. At intervals of some weeks he transferred the sack to a second and then to a third chicken. After this he found the type had changed to avian. His work has been both confirmed and denied.

Raw subcultured strains of human, bovine, and avian tubercle bacilli on artificial media containing glycerin for twelve years, all retained their characteristics and selective appearance, and were readily identified as distinctive types. Animals injected with culture of nine years' attenuation showed no ill effects. In no case did tuberculous symptoms develop; post-mortems were negative. All types lost their ability to attack the tissues of animals for which they had previously a predilection. They were apparently saprophytes.

Some experimenters convince themselves that transformation of one type into another is a simple procedure; others, equally competent, repeat their work and feel certain that metamorphosis never occurs. In the presence of such contradictory results, the proper attitude is one of wholesome but thorough skepticism.

#### Bovine Tuberculosis

Tubercle bacilli found in man and cattle usually fall into two groups designated as human and as bovine. Their differences on media and in virulence to certain animals place the two varieties at extremes with a few strains of each showing variant characteristics. The difference of these two types is probably stable because of long residence in different hosts.

Human tuberculosis is mainly a man to man infection through sputum. Pulmonary phthisis caused by

the bovine organism is rare. It occurs about once in every two hundred cases collected from the literature in which the strains of bacilli found in the sputum have been studied. Bovine tuberculosis in man is pre-eminently a disease of childhood. Its incidence tends to increase inversely with the age of the child. In children, 23.8 per cent of generalized tuberculosis, 40 per cent of tuberculosis of the cervical glands, and 49 per cent of abdominal tuberculosis are due to the bovine type.

At all ages the bovine variety causes 5 per cent of the disease of bones and joints, 10 per cent of the tuberculosis meningitis, and 5.5 per cent of generalized tuberculosis, 25 per cent of the enlarged lymph glands, and 30 per cent of the tuberculosis of the abdominal organs. The bovine variety disfigures and cripples. It brings its victims to many serious operations and kills about 11,000 persons in the United States annually.

### Avian Tuberculosis

Avian tuberculosis is one of the most common diseases with which the poultry raiser has to contend. Fowls particularly, and also pheasants, turkeys, pigeons and wild birds in captivity suffer from the disease. Ducks and geese are relatively exempt.

The pathogenicity of the avian bacillus for mammals is low, but the more recent evidence shows it is more frequently the cause of disease than was once supposed. Guinea pigs, which are highly susceptible to human tuberculosis, possess considerable immunity to tuberculosis gallinaceus. Rabbits, though resistant to human strains, succumb readily to the avian variety. Rats and mice develop the disease spontaneously from the avian form.

The English Commission found that the avian tubercle bacillus caused non-progressive tuberculosis in hogs. Mohler and Washburn were able to infect swine by feeding avian tissues to them. Hastings, Halpin, and Beach found tuberculosis cervical and mesenteric glands in hogs fed upon such tissues six months before. Whether the avian bacillus can produce extensive tuberculosis in hogs is best decided after further investigation. It is able to cause condemnation of a part if not the entire hog, and to this extent assumes greater economic importance. Calves, goats, and colts fed on the avian bacillus may develop lesions in the intestines and mesenteric glands. Subcutaneous injection in cattle produced a local reaction, but

no generalized tuberculosis. The ability of the avian bacillus to ascend the biological ladder and cause tuberculosis in man is of great interest. Rabinowitch and Plimmer have reported this type of infection in monkeys that have died in captivity. Several German authors, notably Lowenstein, have described cases of tuberculosis gallinaceus in man. The mesenteric glands were usually involved. In two cases the kidneys were infected and a mild septicemia was present. Both reacted to avian tuberculin only and became afebrile after treatment and remained so.

Tuberculosis fowls undoubtedly reach the table. The emaciation and striking appearance of the organs, particularly of the liver, greatly reduce the consumption of markedly diseased fowl. The usual methods of cooking probably kills all organisms. Infection may follow the eating of eggs of tuberculous hens, since their eggs may contain a large number of bacilli. Certain of the more common methods of cooking will not destroy all of the bacteria. There is little reason to believe this strain of the tubercle bacillus plays an important role in the production of human illness and mortality.

Both the bovine and the human bacillus are capable of attacking man indirectly through many species of animals. Rothe has described rapidly fatal spontaneous tuberculosis in rabbits, due to the bovine bacillus. Rats, mice, and guinea pigs may acquire the disease from either source.

### Tuberculosis Secondary in Man

Certain French observers believe tuberculosis to be very common among cats and dogs. Cats get the disease from eating tuberculous milk, raw meat, or from association with phthisical patients. While the disease commonly attacks the mesenteric glands, cutaneous lesions in the region of the throat or breast are not uncommon. Griffith obtained the bovine organism from the mesenteric glands, pleural fluid, and muco-pus from the trachea of a cat, dead of tuberculosis. This animal suffered from a frequent short cough many weeks before its death. Cats that are emaciated, that cough, have diarrhea, or ulcers about the face or neck which do not heal readily should be regarded with suspicion.

Tuberculosis in the dog is not rare, particularly in those closely associated with tuberculous owners. Raw meat or unboiled milk may also be a source of infection. Petit reports its frequent occurrence among dogs owned

by restaurant keepers in Paris. He attributes the disease to ingestion of sputum from spittoons. Tuberculosis in dogs may be well advanced before being suspected, and for this reason offers a special menace to their masters. A chronic cough or obstinate ulceration of the skin should cause a dog to be watched.

Parrots and canaries are susceptible to human and bovine tuberculosis. They may acquire the disease from patients. Friedburg and Frohner believe that infection in parrots is commonly an inhalation disease due to human bacilli, but that it may be acquired through food also. With these exceptions, birds are strongly resistant to mammalian tuberculosis.

### Equine Tuberculosis Rare

Equine tuberculosis is rare. As a source of human infection it has academic rather than practical interest. The same is true of phthisis in the donkey and in the mule. Foals fed upon cow's milk or horses kept with tuberculous cattle may acquire the disease. The horse may be infected with either the human or avian bacillus, but the bovine variety is usually the cause of the disease.

Both sheep and goats are reputed to have considerable resistance to tuberculosis. This appears to be due to living conditions more than to natural immunity. The ratio of the infected to the normal in sheep is about one in five thousand. The rarity of the disease is due largely to outdoor life and lessened opportunity for infection. Where goats are kept alone the disease is rare; when they are housed in groups or with cattle it occurs. Both the sheep and the goat have tuberculosis when inoculated with the bacillus.

Of the hogs slaughtered in the United States under Federal inspection, 65,838 or 0.15 per cent were condemned on account of tuberculosis during the fiscal year 1919. Approximately 65 per cent of the animals killed in this country are slaughtered at abattoirs under Federal inspection. In the remaining 35 per cent, tuberculosis is probably higher than in the swine sold to come under inspection. In the German slaughter houses from 2 to 4 per cent of the pigs are tuberculous; in Denmark, from 10 to 14 per cent. The human and avian tubercle bacillus may produce tuberculosis in hogs, but the bovine variety, in the great majority of instances, causes uninspected, uncooked pork to be a source of infection to man.

Less than twenty-five years ago,

the great Koch stated that "human tuberculosis differs from bovine and can not be transmitted to cattle." As to susceptibility of man to bovine tuberculosis, it was not absolutely decided, but one was "nevertheless, already at liberty to say. . . . the infection of human beings is a rare occurrence." He had hardly finished his pronouncement before confronting two horns of a dilemma. He had either to retract or to admit the great mass of evidence of many able investigators was out of harmony with his statement. The passing years have confirmed his error.

Research and experience have shown a closer relationship, not only between the human and the bovine bacillus, but between other members of the "acid-fast" group. The thin partition of slight variation in morphology, the amount of growth on glycerin media, and difference in virulence to rabbits and to calves, in the presence of so-called atypical forms of each strain which closely approach the biology and morphology of those of another, have proved insufficient to prevent questions concerning meta-

morphosis of types. The avian, bovine, and human bacilli are within certain restrictions capable of producing lesions reciprocally though not always typically.

Difference of variety is probably the result of long continued sojourn in the bodies of different animals subject to their body fluids and temperatures. Today the majority of observers hold types are stable because of long residence in different hosts. Tomorrow it may be necessary to accept the view that characteristics of types are slowly labile.

Tuberculosis is not a provincial problem of a species, but a worldwide one, co-extensive with the animal kingdom. The veterinarian, in this study of the disease, must run the biological scale from the lowly blind-worm to the anthropoid ape. The physician, in his endeavor to comprehend the "acid-fast" must descend the ladder of animal life even unto the lizard. He and the veterinarian will meet at many points to join hands in search of the secrets of nature essential to the prevention of great economic loss and suffering.

## Foot Fitting is a Science

By H. A. MEYER, H. A. MEYER SHOE COMPANY, CHICAGO

WE HEAR a great deal about the evils of "shopping around" for medical service and of the ease with which such "shoppers" become the dupes of quackery and charlatanism in contrast with the safety of reliance upon dependable men and demonstrated method. In view of the fact that the feet demand the same discriminating attention that is accorded the rest of the anatomy, it is surprising with what breezy irresponsibility the general public shops around for shoes and with what indifference they disregard the fundamental principles of foot fitting. Fitting feet is the essential thing, and its achievement involves a high degree of scientific knowledge together with a generous measure of good common sense on the part of the shoe salesman. There are multitudes of shoe fitters, but when you do finally find a man who really knows how and takes the trouble correctly to fit your feet, stick to him. Really to achieve foot-fitting, men cannot receive their training academically. They must get it through careful, everyday study of feet, and a thorough, practical understanding of the definite sort

of last and pattern needed correctly to fit a distinct type of foot.

The intelligent attention which the American shoe designing, shoe making, and shoe retailing trade have given this subject in recent years has evolved standards of correct and corrective shoe construction and of foot fitting which a few years ago were not even known to the shoe fraternity. We have got down to fundamentals and have learned actually to fit feet through the building of shoes in many and varied types and combinations of measurements. These principles are being applied to correct the errors which resulted from the older way of thoughtless shoe selling.

For every normal or nearly normal foot everyday foot comfort is now made available to those who desire it. There are three general types of feet into which the great majority of men's feet may be grouped: (1) the relatively high, well knit, fully developed arch, the foot which through proper care, exercise, and well adapted shoes has had a fair chance to function fully; (2) the more prevalent type of foot in which arch trouble in some degree has become

established and is the fruitful cause of unwarranted fatigue from muscular strain and lax ligaments; these feet can in most cases be "brought back" by common sense care, a reasonable amount of suitable exercise, and the right type of shoe; (3) the flat foot which in extreme cases calls for the guidance of a foot specialist or orthopedist in fitting. No retail shoe man should take it upon himself to prescribe a shoe for an extreme case of this kind. A correlation of skill, professional and practical, is called for in order to produce comfort for these "patients."

The difficulties formerly encountered in finding adequate shoes for the many varieties of feet were largely overcome when the shoe manufacturer varied his combinations of lasts and patterns on the basis of actual foot measurements on a wide scale and it is now possible to obtain varied types of shoes, all conforming to correct anatomic principles. The contribution of the retail shoe man and of the shoe salesman toward shoe comfort lies in the consistent observation of the types of feet represented by their clientele so that it is possible to maintain a complete, appropriately balanced assortment. A by-product of this observation has been the development of an ethical sense if you please, which holds them to actual fitting of feet instead of the mere selling of shoes. For it is now well understood that it is risky and poor business method deliberately to sell a misfitted pair of shoes. The ethical shoe man is honest about it and, if his stock is lacking the particular type of shoe needed, the customer is made aware of the fact and asked to try again.

(1) Don't try to wear impractical shoes for practical service.

(2) Don't use snap judgment in the selection of the place where you buy your shoes. Scientific foot-fitting is not usually practised in shoe "cafeterias."

(3) Don't fail to bear in mind that your one pair of feet must serve you a life time.

(4) Don't tell your shoe salesman what size you wear. Make it his business to fit your feet.

(5) Don't foolishly allow "eye-style" to supersede common foot-sense when buying a pair of shoes.

(6) Don't sacrifice your comfort by requiring a foot-fitter to do impossible things. Vanity and foot-fitting are far removed.

(7) Don't buy price in buying shoes. It is only relative, while good, honestly made, comfortable shoes are always an economy.

# A Course in Personal and Community Hygiene

## Syllabus of a Lecture Course for Freshman University Classes

BY ROBERT T. LEGGE, PROFESSOR OF HYGIENE, UNIVERSITY OF CALIFORNIA, BERKELEY, CAL.

**A**FTER many requests from educators in various institutions of learning for an outline for a regular one semester, two unit course, consisting of twenty-eight lectures on Personal and Community Hygiene, the following syllabus was compiled to offer some solution to standardize such an academic course.

Instruction should be as practical and definite as possible, fully illustrated by charts, models, and lantern demonstrations, as well as to be supplemented by readings, sections, and conferences. Two mid-terms and a final written examination should be required to pass the course.

As the majority of our universities and colleges possess military units, it becomes necessary to offer prescribed military hygiene, which has been applied in relation to the respective headings.

In the event that the syllabus is to be used in women's or co-educational colleges, it is recommended by my colleague Professor Ruby L. Cunningham, that such lectures marked by an asterisk (\*) be substituted by the outline of lectures found under addenda.

### Lecture I

*General Introduction.*—Definition of Hygiene and Sanitation—Ancient ideas and beliefs of disease—Mosaic Laws—Early Christians—Era of Pasteur—Modern conception and development of the Science of Medicine and New Public Health in contrast to the Old—Relation to military campaigns—Our duty in preventing disease, respecting health laws and scientific medicine.

*Note:* If a student's Health Service is established on the campus its purposes may be discussed.

### Lecture II

*Parasitism and Germs.*—Mistletoe on plants and vermin on animals not necessarily fatal to host—Bacteria discoveries by Leuwenhoeck, Pasteur, Koch and Lister—Pathogenic and non-pathogenic bacteria—Structure—How they reproduce—Types—Spores and Toxins—Rôle played in disease—Protozoa, fungi and filterable viruses.

### Lecture III

*Source and Mode of Infection.*—Rôle in infection played by animal and vegetable parasites—Short life of disease germs outside of body—Portals of entry into body—Contact not air borne—Relation of focal infections—Droplet infection—Water, Milk, Food, Insects, Prostitution, Dressings and Human Discharges.

### Lecture IV

*Immunity.*—Explanation of Immunity—Vital resistance—Different kinds, natural, active and passive—Examples—History of vaccination—Jenner—Typhoid vaccination—Value in army—Antitoxin—Diphtheria immunization—Schick Test—Toxin and antitoxin—Rabies—Phagocytosis—Anaphylaxis.

### Lecture V

*Carriers and Contacts.*—Importance of recognizing early stages of disease—Missed or mild cases—Contacts—Control by laboratory means—Isolation—Periods of incubation—Carriers—Types—How they infect—Control—Tests for disease.

### Lecture VI

*Rôle of Insects in Disease (Mosquitoes).*—Types and differentiations—Malaria and yellow fever—Death of Lazear—Mosquito control.—*Flies:* Breeding places—Control—Diseases carried.—*Lice:* Kinds—Typhus and trench fever—Death of Ricketts—Delousing in army.—*Fleas:* Rat—Plague—Methods of extermination.—*Intestinal Worms:* Prevention.

### Lecture VII

*Skin.*—Anatomy and physiology of skin—Heat mechanism—Relation of cold, heat, exercise, diet and clothing—Cleanliness misleading for disease prevention—Importance of bathing—Prevention of the common skin diseases—Hair, nails and mucous membrane.

### Lecture VIII

*Exercise and Rest.*—Physiology of exercise—Effects of exercise on muscles, skin, heart and lungs—Results of lack of exercise—Benefits derived from exercise—Special exercises for constipation and postural correction—Kind and time for exercise—Army

setting up exercises and marching—Causes and effect of fatigue.

### Lecture IX

*Clothing and Housing.*—Hygiene of clothing—Materials—Physical properties, wool versus cotton—Ill effects of tight garments and coddling—Under and over garments.

*Housing.*—Regulations as to cubic feet air space in army and industry—Overcrowding—Ventilation, illumination, sites, etc.—Relation to tuberculosis.

### Lecture X

*Feet and Shoes.*—Normal foot—Contrast with infants—Muller's line—The arches—Munson army shoe vs. pointed and high heeled shoes—Army methods of shoeing troops—Correct position in standing and walking—Flat feet, correction and exercise—Stockings—Deformities: corns, warts, bunions, sweating feet, blisters, broken arches, hammertoes and ingrowing nails—Chilblains and frost bite.

### Lecture XI

*Oral Hygiene.*—Teeth—Deciduous and permanent—Explanation of a cross section of tooth—How caries is produced—Preservation of the six year molar—X-ray in dentistry—Dental focal infections—Necessity of removal of hopelessly decayed teeth—Bad effect of over-dentistried teeth—Need for prompt filling of caries—Pyorrhea—Importance of proper occlusion—Cleanliness of teeth—Mastication of food.

### Lecture XII

*Food.*—Sanitation of foods—Pure food movement—Dangers of food handling by human contamination—Carriers—Diseased meat—Food poisoning—Botulism—Food allergy—Vitamins—Diseases due to lack of same—Malnutrition in children—Factors: physical defects, insufficient or improper food, food habits, fatigue, poor home hygiene—Behavior of food substances as fat, carbohydrates, proteins and salts, iron—Functions of each.

### Lecture XIII

*Food (Continued).*—Physiology of digestion and metabolism—Calori-

metry of foods—Engine vs. human machine—Well balanced diet—Army ration vs. millionaire's—Psychology of cleanliness, flavor and cooking—Production and preservation—Diseases carried.

#### Lecture XIV

*Hygiene of Special Senses.*—Normal eye—Accommodation—Eyestrain and its causes and prevention—Different types of errors of refraction and their correction—Muscle insufficiency—Hygiene of light—Ears—Cause and prevention of defective hearing—Foreign bodies—Discharging ears—Effects of diseased tonsils and adenoids—Speech defects.

#### Lecture XV

*Mental Hygiene.*—Importance of emotions—Instincts and heredity—Psychic disturbances of adolescence—Control of the moral sense—Conservation of nervous energy—Prevention of "nerve leaks"—Overcome emotional disturbances, sexual perversions, social irritation and high tension—Agencies that improve the nervous system.

#### Lecture XVI

*Sex Hygiene.*—The phyletic activities—Period of puberty—Physical changes and psychological changes—Internal and external secretion of the testes—Reproduction—Masturbation—Emissions.

#### Lecture XVII

*Sex Hygiene.*—Sublimation of sex thoughts, imaginations and desires—Continent life and the single standard of morality—Penalties of illicit sexual intercourse and the end results of sowing wild oats.

#### Lecture XVIII

*Veneral Diseases.*—Nature's retribution for illicit sexual immorality—Gonorrhoea—Acute symptoms—Chronic stage—Effects on organs—Innocent wife and child—Eyes—When is a person cured?—Chancroid—Syphilis—Symptoms—Danger of active lesions and chronic stages—Wasserman tests—Prophylaxis in army—Suppression of prostitution and segregated districts.

#### Lecture XIX

*Water Supply.*—Its relation to life—Sources—Physical properties—Hard and soft water—Role of saphrophytes—Methods of municipal purification—National agents—Chemical, sand filter, storage and sedimentation—Water-borne diseases—Methods of testing water—Wells—Prevention of pollution and testing—Swimming pools—Treatments—Bathers require-

ments—Bubbling fountains—Tin cups.

#### Lecture XX

*Waste Disposal.*—Old Ideas—Distinction between litter and waste—Garbage—Manure—Incinerators: field and municipal methods—Dangers of human feces on ground—Stream and well pollutions—Hookworm—Sanitary privy and army latrines—Pail system—Description and explanation of the septic tank—Modern plumbing—Modern sewerage—Sewer gas—Sewerage disposal and methods of treatment.

#### Lecture XXI

*Air.*—Composition—Outline physiology of respiration—Pettenkofer's idea of increase of CO<sub>2</sub> not practical—Effect climate and season—Temperature—Humidity—Sewer gas fallacy—Physical factors—Air currents—Drafts—Crowd air, odors, and dust—Pathogenicity of dust practically nil—Industrial processes: fumes, gases and dust—Methods to take test temperature, humidity, and air currents—Effects of rarified air in mountain climbing and aviation—Army cubic feet requirements.

#### Lecture XXII

*Ventilation and Heating.*—Changes of air produced by presence of human beings—Effect of high temperature and humidity on the body and peripheral parts—Diminution of oxygen or the increase of carbon dioxide or organic matter as odors, dust and bacteria—Importance of air currents—Research conducted along these lines—Hill, Lee, and Kimball—Accepted standard: cubic feet per minute, velocity, temperature and saturation—Mechanical ventilation and heating—Cross window ventilation—Jacketed stoves, fire places, steam and hot air furnaces.

#### Lecture XXIII

*Boards of Health.*—Aims and purposes—Personal—Vital statistics—Areas, classes, and causes of good and bad community health conditions—Determining death and birth rates—Recording certificates—Comparison of morbidity and vitality in rural and urban districts—Sanitary engineering—Epidemiologist and Public Health Laboratory: their respective functions—Public Health Nurse—Federal Public Health Service—Red Cross and other agencies.

#### Lecture XXIV

*Tuberculosis.*—Cause of the disease—Prevalence—Varieties of the disease—Disease an infection of infancy—Building up resistance—Checking

by milk pasteurization and care of sputum, careless consumptive—Housing and industrial conditions—Benefits of sunlight, fresh air and hopefulness of early treatment when incipient signs appear—Von Pirquet's reaction—Early signs of the disease—Tubercular testing of dairy cattle—Social machinery, education, sanatorium, preventorium, clinics, Red Cross Stamps—Individual's responsibilities.

#### Lecture XXV

*General Public Health Campaign.*—Control of communicable diseases—Infant mortality: its causes and prevention—Pure milk and food—Rural versus urban conditions—Reasons for the greater mortality, morbidity and physical defects in rural districts—Remedy—Necessity of school supervision and sanitation.

#### Lecture XXVI

*Isolation and Disinfection.*—Old conception of quarantine—Newer public health of isolation and disinfection—The relative slight importance of fumigation—Asepsis and antiseptics—Sterilization—Pasteurization—Its application to the departments of public health, medicine and surgery.

#### Lecture XXVII

*Military.*—Necessity of instruction—Selection of recruits: age and height—Causes of rejection—Sanitation of camps—Latrines—Waste disposal—Stables and mess houses—Location—Improvised incinerators, showers, fly traps, etc.—Fly menaces—Camp diseases.

#### Lecture XXVIII

*Degenerative Diseases.*—How can longevity be increased—Span of life at present—Important diseases, viz.: arteriosclerosis, heart and kidney diseases—Significance of high blood pressure and urinary examinations—Effects of overstrain, nervous excitement, overeating, auto-intoxication, focal infection, syphilis and alcohol—Prevention: importance of medical examinations, diet, exercise, and rest—Avoidance of constipation, chilling, and diet rich in purin bodies.

#### Addenda

The following lectures may be substituted for those marked with an asterisk.

*First Aid.*—What to do until the doctor comes—Dressing of wounds and use of antiseptics—Types and control of hemorrhage—Application of tourniquets—Shock and fainting—Applying of splints to fractures—Burns—Rescue methods—Prone pres-

sure method of artificial respiration—Prevention of accidents.

*Reproduction.*—Types of reproduction found in plants and animals—Examples of the various types with a consideration of their advantages and disadvantages—Morphology of plants and anatomy of animals necessary to the consideration of reproduction with especial attention to the

anatomy of the pelvic organs of women—Human reproduction—Development of the embryo and fetus—Parturition.—Menstruation, normal and abnormal—Hygiene of the menstrual period.

*Adolescence and Secondary Sexual Characteristics.*—Anatomical, physiological, and mental changes occurring during puberty with especial consid-

eration to adolescent psychology—Impulses for self-preservation and for race preservation—Normal and abnormal direction of these impulses.

## Radium—Its Sources and Uses

BY EDWARD L. BERNAYS, NEW YORK CITY

**R**ADIUM, the most mysterious and powerful element known to science, has in the past decade taken its place as one of the valuable therapeutic agents. As a method of treatment in the case of cancer and other malignant fibroid growth, radium has demonstrated its great value both actively and passively, in that it frees the patients from a fear of the knife which in many cases deters them from applying for medical aid until the growth has reached an advanced and incurable stage.

Radium is mined chiefly in America. It is derived from carnotite ore found largely in the Undark mines of Colorado and Utah. The ore from which it is derived contains merely minute particles of the substance. Two hundred and fifty tons of ore treated with an equal amount of chemicals and water yield but one milligram. The ore is found in narrow seams of the ground and is sorted and packed in one hundred pound sacks and is transported sixty miles to the nearest railroad, on the backs of burros and mules. It is then shipped in carload lots 2,900 miles across the continent. One of the largest of the extraction plants is that of the United States Radium Corporation at Orange, N. J.

In appearance radium is a whitish substance somewhat like common salt, with a white metallic lustre. Radium is originally obtained from its ores in the form of hydros sulphate, chlorid, or bromid, and it is usually sold and used in the form of these salts. These are all white or nearly white, substances. Radium cannot be seen even with the microscope in its natural state. It is formed by the decay of uranium, an exceedingly slow process. Radium itself decays and changes to other elements, but it takes 3,600 years to effect the change.

In addition to the therapeutic uses of radium, it has been linked up defi-

nately with the safety movement, in that when combined with zinc sulphide, it becomes luminous and makes a sure and warning signal for danger spots in the dark. Its value in lighting up, as an undark luminous material, dangerous corners in mines, power switches in plants and factories, and even in such common and household uses as illuminating poison bottles so that they cannot at night be mistaken for medicine, has been proven a success.

Radium has power to destroy all tissues and bones. In this power lies its great therapeutic value, because by proper application it can be used to do no harm to healthy tissues, while it destroys unhealthy tissues and malignant growths.

The discovery of radium as a therapeutic substance was an acci-

dent. M. Henri Becquerel was affected by a piece of radium which he had in his pocket. From the analysis of the sore with which he reviewed has grown the science of radium therapy.

In therapeutic treatment, radium is used usually in salt form, generally the bromide. This is enclosed in a glass capsule. The alpha rays and some of the beta rays are shut off, as these sometimes result in erythemic eruptions of the skin and serious burns. The glass capsules are often enclosed in a metal applicator or a tube of platinum, lead, gold, silver, or brass. A rubber tube eliminates secondary rays. The action of radium is to lower the vitality of diseased tissue and to invigorate surrounding structures. It has been found of particular value in cancer of the skin,

Radium in the process of extraction in the plant of the United States Radium Corporation at Orange, N. J. In the large vats are contained strong acids and chemicals by which the carnotite ore is reduced to its pure form and finally to the radium salt.

especially on the face and around the eyes, and alae of the nostrils. Cancer of the uterus has been treated with great success. Various glands of the body have also yielded readily to treatment, especially tuberculous glands which have not yet suppurated. Papilloma of the skin, warts, etc., have been treated successfully with the application of approximately ten milligrams.

Radium emanations are used extensively in place of the radium itself. The emanations are in the form of gas artificially made from a solution of radium salts, or they may be secured from natural radium springs. Radium emanation is reliable therapeutically; it stimulates normal cell life and destroys pathogenic bacteria. It is said to increase the hemoglobin and is tonic to the entire nervous system.

Chemically analyzed, radium has an atomic weight of 226.5 and is classified as one of the alkaline earths. In its natural process of disintegration it endures for about 3,600 years. Atomically it is highly concentrated.

The rays given off at the moment of the explosion of the radium atom are the alpha, beta, and gamma rays. The alpha rays consist of minute particles of matter charged with positive electricity and travelling at the rate of 20,000 miles per second. Their penetration of the air is only three inches approximately. Beta rays given off during the explosion of the radium atom are composed of negatively charged atoms. Their velocity is one hundred thousand miles a second. The gamma rays are, it is said, vibrations of the ether. The radium emanation is brought into existence through the eruption of the radium atom and is a gas. For therapeutic purposes it is compressed in needles or cylinders. So great is its power that one gram of radium contains sufficient energy to raise a dreadnaught battleship one hundred feet in the air. There are in the world today three ounces of radium.

The development of radium mining has been exceedingly rapid in the past decade. It is probable that new radium deposits will be found constantly. Already more radium has been taken out of the carnotite district than the most competent authority predicted would be found there. Originally radium was secured from pitchblende in Austria. Now almost the entire product of the world comes from the United States.

Radium deposits have also been discovered in Argentine, in England, in

Test tubes and other chemical apparatus are utilized in the extraction processes, as the forms reduced from the ore become simpler and simpler.

Canada, in Portugal and in Russia. There is every reason to believe that available sources of supply will be increased greatly and that there will come the development of radium extraction from ores other than carnotite. The radium supply of the world

is so promising that its use should not be limited to the treatment of cancer and allied diseases, but also for the preparation of undark luminous material which makes possible the greater development of the radium industry. It is valued at \$3,260,000 an ounce.

## Toronto School Health Service

THE method of administrating the medical inspection of Toronto schools is described in *The Public Health Journal* by Eunice H. Dyke, Director of Public Health Nursing, Department of Public Health, Toronto. The close relationship of the school health service with other community services is secured through the coordinating agency of the City Hall. Eight district offices of the Department of Public Health have been found to be necessary to serve a population of 525,000.

Each district office is in charge of a superintendent of public health nurses to whom the field nurses of the district report at noon. The nurse, responsible for the nursing service in the schools, is one of the five special supervisors who are responsible to the director of public health nursing for the development of certain branches of nursing.

The school population of Toronto is approximately 85,000, accommodated in 92 public and 28 separate schools; 2,147 teachers, 13 doctors, 26 dentists,

84 nurses, and 25 dental assistants are employed in these schools. The Department of Public Health for the last four years has provided health service for the Board of Education and the Separate School Board.

Three aims for health service in the schools set forth by the supervisor of school nursing are: (1) control of communicable diseases; (2) correction of defects; (3) health education.

A step in the direction of education and prevention is demonstrated in the increasing number of health talks the public health nurses have been able to give. In the school year 1919-20, the public health nurses in Toronto recorded 64,000 treatments given to school children and only 2,800 health talks. The following year treatments were reduced to 28,000 by a skilful shifting of responsibility upon the mothers and health talks increased to 5,000 in addition to which many more were given by the teachers. The service aims rather to examine and refer to clinics or physicians than to give specific treatment.

# Baltimore's Public Laundries

FOR twenty-one years Baltimore has run in connection with its public bath houses public laundries in which the housewife from the tenements may do her family washing or the odd job man wash the clothes on his back. The story of the success of the Baltimore laundries

For the sum of ten cents the patron receives a towel, a half ounce piece of toilet soap, and a ticket. When his bath is finished he puts on his trousers and coat, and presents his ticket to an attendant who gives him one-third of a bar of laundry soap and assigns him to a set of laundry tubs

Public laundry at Walters Baths No. 1, Baltimore, where men may wash their clothes for a few cents. During the past year 7,000 men took advantage of the laundry's facilities.

is told by Robert F. G. Kelley, secretary and superintendent, Free Public Bath Commission, Baltimore, in *The American City*.

Located in the center of a thickly congested foreign district, the first bathhouse was open at first four days to women and two days to men, but as more and more men came to take advantage of the laundry facilities and the type of population of the neighborhood changed, in 1920 it was made exclusively a laundry for men. During that year, the laundry had a patronage of 7,000, while in the unemployment period in the early months of 1921, the patronage totaled 3,875.

The men who take advantage of the bath and laundry are often oyster dredgers up from a long trip down the bay; odd job men from cheap lodging houses nearby, or tramps who have heard from other travelers of the road of a chance to clean up. Sometimes a cripple is seen scrubbing out his clothes. Sometimes the patrons are men sent over from one of the Rescue homes. During the war many soldiers from the camps took advantage of the laundry facilities. The slight charge was not made for them nor is it made for men who have no money.

where he proceeds to wash his clothes. If he wants to launder his coat and trousers—he has brought a blanket along for such an emergency perhaps—he does so. While his clothes are drying he enjoys a quiet smoke and talk with the other men.

So successful and popular was the public laundry in connection with

Walters No. 1, that when the four other public baths were built, laundries were installed. As these were in residential neighborhoods they were opened to women. Here a woman can do her family washing and ironing at a cost of 28 cents in four hours while the children play in an adjoining playroom. The 28 cents has covered 20 cent charge for four hours in the laundry, 1 cent for bluing, 1 cent for starch, and 6 cents for soap. The women who patronize the public laundries often live in tenements or rooming houses where laundry facilities are inadequate or entirely lacking.

Walters No. 3, patronized by colored women, is by far the most popular of the Baltimore laundries, having accommodated 13,998 during 1920. To these colored women living in crowded tenements and alleys the public laundry offers their only means of cleanliness.

The attendance for the year 1921 at the laundries was as follows:

Walters No. 1—	
For men only.....	12,689
Walters No. 2—	
For women only.....	3,235
Walters No. 3—	
For colored women.....	12,980
Walters No. 4—	
For women only.....	3,523
Greenm't Ave.—	
For women only.....	2,499

Total.....34,926

To city officials who are contemplating the establishment of public laundries, Mr. Kelley makes the following suggestions: That there should be a playroom adjoining the laundry where

Walters Baths No. 3 where women from nearby tenements or rooming houses may do their family washings. A playroom is maintained for the children.

mothers can leave their children; that advertising is often necessary at first; that employees should be selected with care as a poor employee can keep many patrons away.

Dr. Donald B. Armstrong, of New York City in writing of public laundries several years ago said that of the fifteen institutions in the United

States, five of the best were in Baltimore.

Public laundries are of vital importance to the city in Dr. Armstrong's opinion. Affording people an opportunity to be clean gives them an appreciation of health and decency and enhances their moral and spiritual tone.

## Springfield Protects Traveler

SPRINGFIELD, ILL., furnishes every safeguard possible for the health of the traveling public. Its central location, coupled with its historic associations as the city in which Abraham Lincoln lived and in which he lies buried, takes tens of thousands of visitors to the city annually. Last year approximately 100,000 convention delegates alone visited Springfield. Added to these were many thousands of automobile tourists and other travelers.

Particular attention has been paid to the safety of auto tourists. Springfield, a city of seventy thousand, maintains free of all charge to the traveler, five splendidly located and equipped camps. Four of these are located in parks within the city limits while a fifth, instituted this Spring, is situated in the forest preserve of four hundred acres recently acquired by the Park Board along the banks of the Sangamon river, six miles north of the city.

These camps are ideally situated on high ground in shady groves of stately trees. No well water is permitted to be used, the entire supply being drawn from city mains. This is tested weekly by the State Water Survey and complies with the standard required by the Illinois Board of Health. Its source of supply is an underground lake from which it is drawn by a series of drive wells.

Campers are provided with sanitary toilets and shower baths with hot and cold water. Towels and soap are furnished. The camp sites are cleaned every day and disinfectants applied. Garbage cans are conveniently placed and are emptied daily. Furnaces are furnished for cooking and washing purposes and wood is supplied. There is absolutely no element of cost attached to the use of these camps. Everything is furnished free to the visitor. Needless to say, all camps are given ample police protection and their location marked along roads leading to them. The traveling public makes generous use of these camps

during the tourist season which opens in May and runs through to November.

Springfield, through its health department, provides the following health safeguards for the traveling public: a safe water supply, examined weekly; a clean and safe milk supply—all table milk is pasteurized or comes from tuberculin tested herds; all ice boxes, refrigerators, and kitchens in hotels and eating houses examined twice a month; all edibles are required to be in a glass case and windows and doors screened; no sick person or any person with a communicable disease is allowed to work in eating places or handle food. If a case of any communicable disease is found in any hotel or rooming house, the case is promptly removed to the isolation hospital. If the disease proves to be smallpox, all exposures are promptly vaccinated, if diphtheria, all contacts are immunized with antitoxin. All bed linen or kitchen utensils that came in contact with or were used by the sick person are boiled or soaked in a strong disinfectant solution. Warning signs are placed in all public toilets, setting forth information regarding venereal diseases and instructing what to do after exposure. Instructions are given to school children on how to prevent the development of flies. Twelve thousand school children are pledged to drive the fly from Springfield.

### A Plague-Proof Town in India

The only plague-proof town in India was the honor accorded Fraser Town by Sir Harcourt Butler at the first All-India Sanitary Conference, and for twelve years the town has maintained its record and has been a refuge for inhabitants of the nearby plague-stricken cities. J. H. Stephens, engineer of Bangalore, India, tells in the *American City* of the building of the plague-proof town.

The Hindoos could not understand

why plague carried them off in large numbers while it rarely attacked the English occupants of the town. In their ignorance and superstition they ascribed it to the Plague Demon to be exorcised by sacrificial rites or thought that the English were working a spell upon them. They did not realize that their congested housing, their closely abutting buildings, their dirt floors and muddy streets, their vermin and rat infested homes furnished fertile field for the development of the disease.

Fraser town is located on fifty acres of high agricultural land north of Blackpully. The site is well drained. The soil consists of red loam for the upper two feet and hard gravel beneath. Its greater length faces south, the direction of the prevailing breezes assuring a windswept healthful locality. The tract is broken up into one acre building blocks, each acre divided into twenty building sites. Main roads are 99 feet wide; other roads 66 feet; and the streets 33 feet wide.

With the town properly situated and the houses far enough apart, the next problem was to draw up a set of plague-proof rules for the construction of the houses. The first and most important regulation was to keep the town free from dampness. For this reason all roads and streets were countersunk about one and one-half feet below the level of the natural ground. The natural percolation in the upper soil was cut short at each acre block by the countersunk roads and streets thus keeping the buildings quite dry even after the heaviest rains.

To keep out rats and vermin, it was required that basements be not less than one and one-half feet high and that they be built of coarse granite rubble jointed with good cement. Floors were to be of hard compressed tiles. To insure proper ventilation, the roofs were to be covered with Mangalore tiles which keep out the rain but admit of continual circulation of air through the joints. This was an especially noteworthy requirement as the Hindoos usually keep all doors and windows tightly closed.

In the new town Indian children are not forced to play in the gutters—each has his own little yard for playground. The Indians are being taught hygienic living and their children are growing strong and healthy.

The fact that for twelve years Fraser Town has been free from plague should be sufficient evidence of the success of the city's plan.

## Nutrition in Soft Drinks

THAT the soft drink may have nutritional as well as therapeutic value is the thesis of M. E. Jaffa, M.S., consulting nutrition expert, California State Board of Health, set forth in the *Monthly Bulletin*.

Soft drinks may be conveniently divided into four main classes: (1) drinks compounded from artificial flavors, artificial coloring matter, and artificially sweetened; (2) drinks compounded from artificial flavors, artificial coloring matter, and sweetened with sucrose; (3) drinks compounded from fruit juices or syrups; with or without the addition of sucrose; (4) drinks compounded from syrups containing stimulants such as caffeine.

Drinks coming under the category of Class 1 are rarely met with today; they were practically eliminated from the market with the proclamation of food inspection decisions Nos. 138, 139, 142, and 146, which rule against the use of saccharin as a sweetener. They have no nutritional value whatever.

Class 2, comprising drinks containing artificial color and flavor are the most commonly met with and their food value lies mainly in the sugar added. The greater the concentration of sugar employed and the larger the amount of syrup added to the bottle, the higher is the nutritional value. Tests have shown that the average amount of sugar in each drink is about two rounded teaspoonfuls. This class of drink often contains acid, chiefly citric, which has a certain therapeutic and hygienic value though no nutritional value. These drinks do not yield any appreciable amount of mineral matter.

By far the most valuable class of soft drinks, Class 3, consists of those compounded from fruit juices or syrup with or without the addition of sucrose. The mineral matter in the fruit is basic in character and very necessary to offset the acid character of the minerals found in meat, cereals, and eggs. It has recently been discovered that fruit juices contain an appreciable quantity of water-soluble vitamins. Therefore, a carbonated drink containing one and a quarter ounces of condensed pure grape juice will equal in nutritive value about one-half glass of plain or normal grape juice yielding one hundred calories, and in addition will have vitamins and mineral matter which are not present in beverages prepared

from sugar syrup as a basis. This applies only to condensed fruit juices and not to fruit extracts. Likewise a glass of lemonade is rich in anti-scorbutic vitamins and minerals, while the artificial beverage is devoid of these two dietary essentials.

The fourth class of drinks are those compounded from syrups containing stimulants such as caffeine. These have attained great popularity and many varieties are on the market. Coca Cola is the chief beverage on the market to-day which contains caffeine.

The large majority of bottled soft drinks are colored artificially, the exception being ginger ale, sarsaparilla, root beers, carbonated grape juice, and others. The colors used are those permitted by the Bureau of Chem-

istry, United States Department of Agriculture. They have no food value nor do they have any injurious effects on the system. Their main function is to lend a pleasing appearance to the drink, thus psychologically adding to its palatability.

The growing demand for the use of real fruit in soft drinks is encouraging. However nourishing the article is, its value is nullified unless it is prepared under sanitary conditions. Recommendations of the author are that bottled soft drink industries should have (1) clean and sanitary establishments; (2) that they should use only the highest grade of ingredients and that the beverage be prepared in strict accordance with the provisions of the California Pure Food Law; (3) that they use pure fruit syrups and juices to the fullest extent possible.

## Health Officers Underpaid

MANY invidious comparisons have been made between the importance and the wide range of qualifications demanded of the efficient health officer and the salaries carried by important posts in health departments. The subject is at the present time being made a matter of special inquiry in the United States. The inadequacy of compensation, the uncertainty of tenure of office, and certain other factors affect unfavorably the status of health work as a career—facts which are to be taken into consideration in plans to educate sanitarians.

That discrepancies in compensation of health officers are not confined to the United States is brought out editorially in a recent issue of the *Hospital and Health Review* (England) in commenting upon the underpayment of Medical Officers of Health as indicating how little the public really cares about the prevention of disease.

This reads as follows:

In the *Leeds Evening Post* of January 6 there appeared a list of the salaries paid to certain of that town's officials. The tramways manager receives £2,530 per annum, the electricity manager £1,500, the gas manager £1,500, the city treasurer £1,386, the sewerage engineer £1,122, and the chief constable £1,135. We have no doubt that all these servants of the public merit entirely the salaries paid to them in their high offices; and we should expect to find that the medical officer of Leeds was equally well paid for his specialist services, since, like them, he has spent many years in training for his work, and has passed a long probation in the public service.

His yearly payment is however, only £935, and even an assistant in the Town Clerk's department receives more than that. We venture to think that there is no general practitioner with a panel practice in Leeds who is receiving less than a thousand a year, and since the Medical Officer of Health is supposed to be the chief medical officer in his town the position is obviously ridiculous as well as distressing. Preventive medicine, paid a starvation wage, will soon cease to attract the best brains in the profession.

It would appear that the Great City of Manchester is intending to follow the practice of Leeds. We do not know if Manchester looks to Leeds for guidance and enlightenment in matters of public health policy; but it would seem that what Leeds thinks to-day Manchester will think to-morrow, for they are proposing to advertise for a Medical Officer of Health at the salary of £1,500 a year.

The *Lancet*, we understand, refused to advertise in its pages for a successor for Dr. James Niven, the retiring health officer of Manchester because the compensation offered was so painfully inadequate. There are perhaps less than a dozen men in England who could adequately follow up the brilliant work accomplished by Dr. Niven, and yet a salary comparison would offer no indication of his distinction in the world of sanitary achievement. A worthy successor was found, however, which is a noteworthy comment upon the prevailing sense of a high calling among workers in this field. Cities should realize that the city health officer is one of its most important officers and should be compensated accordingly.

## Industrial Physicians in Seventh Annual Meeting

THE program of the Seventh Annual Meeting of the American Association of Industrial Physicians and Surgeons which appears on another page of this issue provides for authoritative discussion of a range of subjects which are directly at the basis of industrial medicine. It is more and more coming to be appreciated that, in addition to the direct relationships which always exist between human activities and human ills, specific occupations have specific bearings, and each industry may well be considered a field in itself. Industrial medicine as a specialty is new. Many observations are to be made, results correlated, and a body of scientific knowledge made available for application toward raising the standard of medical practice generally. The demand of the situation is developing leaders. The contacts and stimuli growing out of a conference of the nature planned for the St. Louis meeting give the best possible impetus toward better work and afford practically the only means of achieving unity on fundamental issues. It is hoped—and expected—that every member of the Association who can possibly attend the meeting in St. Louis will arrange to do so, and particularly that all will attend the business conferences where new policies are framed and future activities planned. The meeting is held just prior to that of the American Medical Association.

## New Problems for the Water Works Engineer

IT HAS been generally assumed for many years past that the colon bacillus as a representative of the commoner intestinal organisms furnishes an adequate index of the potability of water and the efficiency of water purification. Recent observations at Montclair, N. J., and in other places<sup>1</sup> throw a certain doubt upon the validity of this conclusion, and open up the whole question for reconsideration. Nearly twenty-five years ago Klein<sup>2</sup> advanced the view that certain anaërobic spore-formers play a rôle of dominating importance in the causation of diarrheal disease. The observations at Montclair, where two outbreaks of mild diarrheal disease have been associated with a water supply free from colon bacilli but containing large numbers of spore-forming anaërobes, give substantial weight to Klein's contention, although the Montclair evidence is by no means accepted as conclusive by all students of the problem<sup>3</sup>. If the importance of the anaërobes should be substantiated it will obviously be necessary to regard with suspicion water supplies containing gas-formers of any type, instead of attempting as is now the practice to differentiate between supposedly innocuous anaërobes and supposedly significant bacteria of the colon group. Furthermore, our faith in methods of purification like chlorination, which will destroy members of the colon typhoid group, but not the spore-formers, will be seriously impaired if the anaërobes are proved to be of real significance.

## Health Problems Involved in Control of Bovine Tuberculosis

THE very vigorous campaign against bovine tuberculosis which is being carried on in several states under the inspiration of the Bureau of Animal Industry at Washington is likely to mark an important step forward in the progress of veterinary medicine. The problem is a highly complex one, however, and the present movement must be directed conservatively and with a regard for the broad principles of public health involved if it is to accomplish a maximum of good with a minimum of harm.

The first step in this campaign is the separation of reacting from non-reacting cattle by the use of the tuberculin test and this step is clearly a sound

1. Larner, H. B.: Bacillus Welchii in a Public Water Supply as a Possible Cause of Intestinal Disease. *Jour. A. M. A.*, 1920, lxxviii, 276-279.

2. Klein, E.: 1898 and 1899 Supplements to the 27th and 28th Annual Reports of the Local Government Board of Great Britain, containing respectively the reports of the Medical Officer for 1897-8 and 1898-9.

3. Baker, M. N.: B. Welchii and the Montclair Water Supply. Paper read before the N. J. Sanitary Association at Lakewood, N. J., Dec. 9, 1921. Printed by Montclair Water Company.

and altogether useful one. The building up of so-called "accredited herds" certified as free from tuberculosis by the State and Federal Government is an admirable move and the separation of reactors and non-reactors according to the Bang system seems logical and desirable. The cost of equipment necessary to enable the individual farmer to maintain two isolated herds is usually too great to permit of the general extension of the Bang system in its original form, but it seems possible that by cooperative arrangement the principle may be applied to larger areas.

The more enthusiastic crusaders against bovine tuberculosis are not, however, satisfied with the plan which merely isolates infected from uninfected cattle. They desire to slaughter all reactors and it is at this point that the movement threatens to become harmful rather than beneficial to the general cause of public health. The underlying policy of indiscriminate slaughtering of reacting cattle is based on the assumption that all such cattle will shortly become active cases of tuberculosis and will pine away and perish. So far as we are aware this assumption is not adequately supported and there is reason to believe that with cattle as with men you may have a positive tuberculin reaction persisting for many years without practical impairment of physical health and vigor. If such be the case the policy of slaughtering is wasteful and unnecessary.

From the standpoint of the protection of human health there are still more serious disadvantages involved in the propaganda which has been carried on in certain instances by the protagonists of tuberculin testing. It is quite clear that the only possible way in which the general milk supply of the community can be safeguarded is by properly supervised pasteurization. If tuberculosis did not exist as a disease of cattle, pasteurization would still be essential, except for a very small amount of very high grade milk, in order to protect the public against diseases of human origin and the tendency to advocate tuberculin testing and the slaughter of reacting cattle as a measure for the protection of the health of human beings must prove an unfortunate one, if it tends to hold back the movement for pasteurization which is the one hope of securing a really safe milk supply. The slaughter of healthy but reacting cattle is also a direct damage to the public health since it tends to decrease the supply of milk, an increase of which is so much to be desired from the standpoint of national nutrition. It would seem on the whole that the indiscriminate slaughtering of healthy reacting cattle is without adequate justification from the standpoint of the veterinarian and is likely to work direct and indirect harm to human health.

## The Science of Applied Climatics

**A**N EXPERIMENT, or, more properly, a series of observations unique in scope if not in their nature, is represented in the climatic correlations with the general well being of the people in Detroit and New York City which are made possible by researches recently undertaken by The National Research Council through its recently appointed committee for "the study of atmosphere and man." Precise data will be collected over a period of twenty-five years through the analysis of which it is hoped to arrive at an "optimum" of physical conditions for man's health and highest achievement. A tentative announcement of the project appears on another page of this issue of *THE NATION'S HEALTH*.

In England, too, an impetus has been given to the study of natural conditions as affecting human life through the appointment by the Medical Research Board of a committee to study the effects of sunlight, it being recognized that a much wider range of vibrations than is indicated by the solar spectrum influences human life and activity. While physiologic changes at great heights have commanded attention, as have the inimical extremes of tropical and polar regions, no consistent effort to study normal man in his usual habitat has been made on a scale that compares with the body of information that has been collected on artificial conditions of air, light, humidity, and interior ventilation in general. A change of climate is prescribed in such a haphazard manner as to make it uncertain whether any benefit derived is psychic or physical and even the medical profession has no satisfactory basis for the estimate of climatic influences.

While it may be wise to avoid giving undue weight to any single explanation sought for the fluctuating conditions of human health, especially as individuals exposed to the same climatic conditions react at the same time to many variable and imponderable physical and mental conditions, the proposed study should throw much light on the degree of deterioration and needless loss of human life we suffer when we deprive ourselves of the stimulating effect of fluctuating, open-air conditions.

## Compensation for Typhoid

**T**HE Appellate Court of Indiana in a recently reported case has declared typhoid fever to be compensable as an accident under the Workmen's Compensation Act of that state. The facts are, in short, that water from a polluted well was furnished the employees for drinking purposes during working hours. An employee, Karst by name, drank the water and later de-

veloped typhoid fever. The Industrial Board found that the employee "received a personal injury by accident arising out of and in the course of his employment." The cabinet company did not dispute the fact of the polluted well but claimed that award had been given for disability from disease, "for which compensation is not authorized."

The Court in reply bends its logic to conform to the justice of the situation. It disregards the charge that typhoid is a disease for which compensation is not authorized, but declares that the entrance of the typhoid germs into appellee's intestines by reason of drinking the polluted water is rightfully termed an accident because the intestines became inflamed and fever resulted.

The question is, of course, whether this distinction of the Court is sound and defensible or whether it is one which will in the course of time have to be altered and adjusted to meet the various exigencies arising in the fields of law and medicine. It is undoubtedly a distinction but if it is adhered to, then many of the industrial diseases, it may be argued, are compensable not as industrial diseases but as "accidents arising under the Workmen's Compensation Act." Is the entrance of a tubercle bacillus into the anatomy of its unsuspecting host an accident? From one angle, it may be regarded as an accident perhaps, but then it must follow that the term accident is very inclusive and may be stretched to meet the occasion. Such an award may be just, but is it legal?

---

### Research in Vocational Psychology Receives Impetus

THE Psychological Corporation, recently granted a charter by the state of New York, is the first business corporation in the United States whose objects are the advancement of science and whose profits must be devoted to scientific research. Such names as J. McKeen Cattell, Walter Dill Scott, Lewis M. Terman, James R. Angell, Richard E. Dodge, G. Stanley Hall, C. E. Seashore, E. B. Titchener, R. S. Woodworth and R. M. Yerkes assure the broad objectives of this association to bring about the advancement of psychology through its application to educational, business, administrative, and other problems.

What may be expected in the way of developing the field of vocational psychology is indicated by the recently issued report of a year's progress of the National Institute of Industrial Psychology in England in which it is claimed that the methods adopted by the Institute have been shown "to reduce the costs of production, to promote the de-

velopment of individual ability, to eliminate unnecessary effort and fatigue, and to improve the health and well being of the worker." On the basis of the accomplishments of a single year Lord Haldane expressed the belief that "within twenty years a psychological expert will be at the elbow of every manager of a great concern to aid him in increasing the efficiency of his business, promoting at the same time the happiness, health, and comfort of the workers."

Vocational psychology, like medicine and surgery, is advanced by research and by practice, said Dr. C. S. Myers, who is resigning his directorship of the Cambridge Psychological Laboratory to devote the whole of his time to the Institute. Lectureships are to be established, and research posts provided in the principal universities are to serve as local centers for the development of the work.

---

### Epidemiological Constellations

THINKING sanitarians have for a considerable time realized that to speak of a specific organism as the cause of a given disease is a glaring inaccuracy; that the origin of a pathological condition is not to be predicated on a single event, such as the introduction of a particular germ into the living body but rather is the culmination of a considerable series of circumstances which by action and interaction produce a definite physical reaction, a bodily disorder of functionation. Thus there has been a gradually broadening concept of the etiology of sickness, and, while the pendulum swung backward in the earlier days of the bacteriological era when an organic cause was sought for every disease, it moved forward again with the knowledge that while the seed is a necessary factor in disease production, the condition of the soil, no less than the environment, is an equally necessary requisite in the completion of the pathological equation.

Prof. N. P. Tendeloo of the University of Leyden, quoted by Bosma in a recent issue of *The Lancet*, proposes the name of "constellation" for the sum-total of the factors required for a definite pathological process and the several mutual influences of the factors upon each other, *i.e.*, the relativity of the several component parts of the constellation. The removal or alteration of any factor in the constellation changes the final result because a change in the equation of disease is thereby produced. It is Bosma's plea that Bertrand Russell's dictum that "Every advance in a science takes us further away from the crude uniformities which are first observed into greater differentiation of antecedent and consequent and

into a continually wider circle of antecedents recognized as relevant" be accepted in order that we may achieve exactness by the determination qualitatively and quantitatively of the complete constellation of external and internal factors leading to an end result.

From the viewpoint of epidemiology, this argument, which at first glance is as abstruse as Einstein's theory, is of the utmost importance. It means that no single factor produces mental or physical subnormality but that a chain of co-related circumstances focuses inevitably to a certain predetermined end. Therefore in the study of a disease and in the formulation of measures for its control, it is necessary to determine with as great accuracy as possible every fact relating to the seed, the soil, and the environment. Every student of sanitary history can recall instances in which entirely empiric methods have accomplished the control of a given disease, yet at great cost, much hardship and a tremendous expenditure of blunderingly applied effort. The constant aim of hygiene is the evolution of exact methods of disease prevention methods which will accomplish a desired result with mathematical exactitude. Since a constellation is a definite equation, it is evident that the slightest alteration in any factor entering into it will alter the final result, hence a knowledge of all the component parts of the problem permits its solution in as many different ways as there are component elements in the constellation. Thus the control and prevention of disease is a many-sided affair and the sanitarian of broad knowledge has the choice of many different points at which to attack and no element in disease propagation and spread is too small to merit his careful study and attention, since upon the relativity of these depends the final outcome.

### Golf and the Law of Reversed Effort

IT HAS been often said that golf is a psychological game, a statement which there is no gain-saying, but one which is frequently accepted as meaning that there is something inherently mysterious about the sport itself. This is not true. Anything which brings into play the active conflict between imagination and will, which requires the formation of judgments and the execution of coordinated acts, brings the psychological element strongly into play, and this factor is prominent in many games besides golf. Thus when one says that the player hasn't his mind on the game, it is merely a method of describing a mental state in which imagination is roaming free—"wool-gathering"—or one in which it dominates the will.

Golf is a jealous mistress, demanding of those

who worship at her shrine that they let no thought stray afield, visiting swift and terrible punishments upon the infractors of this rule and granting to those who obey it, sweet surcease from worry and the priceless boon of mental relaxation and physical restoration. But this is not enough. Coué has laid down a theorem with which every sportsman should be familiar and which will explain to the discouraged golfer the source and the cure of many of his difficulties. This is known as the law of reversed effort and is stated in the following terms: (1) When the will and the imagination are in conflict, the imagination always wins; (2) in conflict between the will and imagination, the imagination varies in direct ratio to the square of the will.

For example: the player is on the tee; on the right is a yawning chasm, directly ahead is the beautiful fairway with the flag jauntily snapping on the distant emerald green, to the left is a bunker and trap; the last time he played he sliced into the ditch and the time before that, he landed in the sand; he is already two down and three to go, he *must* win the hole. He tees up carefully, adjusts the ball neatly and arranges his stance with meticulous scrupulosity. All the time his imagination is nagging him in much the same manner that a wife on the back seat talks to her husband at the steering wheel. "Watch out for the ditch! Keep out of the bunker!! If you aren't careful you'll dub, whiff, fozzle, hook or slice!!! Keep your head down!!!! Think what the crowd at the clubhouse will say if you let this Smith trim you!!!! You can't do it, you can't do it, you CAN'T do it, YOU can't do it!!!!!" and your will is answering, "You will do it, I'll make you do it, you shall do it!!!!!" The club comes back slowly, reaches the top of the swing, comes through with a snap of the wrists; there is a dull plunk; the club follows through; the player lifts his head and gloom descends; he has driven about twenty yards. The intensity of the battle between his imagination and his will has defeated him in spite of an irreproachable technic. His entire mental state, and reflexly his physical state, has been dominated by the fear of failure and therefore failure was foregone and inevitable.

Suppose on the contrary, the player takes his stance, squints at the flag and drives without any thought of the ditch, the bunker or the rough, without undue effort, without worrying about the wind or his grip, passively certain that the ball is going to travel sweetly with a nice, flat trajectory for a full two hundred yards. His mind and muscles are gently relaxed into an unconscious rhythm of movement. A titillating crack, more soul-stirring than the music of a heavenly choir, greets his ear, the ball majestically soars toward

the pin, he is engulfed in a healing balm and peace descends upon him.

The entire game is but a repetition of these two examples, modified in a thousand different ways with brassie, iron, spoon, with niblick, putter, cleek, with sand-trap, water, rough, with hills and valleys, worm-casts and the fallen leaves blushing with autumn. Imagination paints a certain hole as unconquerably difficult and thereafter, it is the player's *bête noire*—the "black beast" created by his own imagination. His ball always seeks a certain piece of rough, because he wills so strongly to miss it that his imagination triumphs. To him, putting on one green is a torture, until some one convinces him that a particular stance cannot possibly fail, and then it is transmuted into a joy. And so the game proceeds, one continual combat between his will and his imagination.

There is a practical application of all of this from a medical point of view. Golf is not a game to be thoughtlessly and miscellaneously prescribed. It is a therapeutic agent of wonderful value in selected cases, but it is no panacea, and, like other methods of cure and health creation, it must be accurately used. Granted a physique capable of indulging in this form of exercise, the physician must also assure himself that there is no psychological hazard in administering it. As in any medicament, the patient must be taught exactly how to use it and he must be warned of the dangers from its overuse or abuse. It is not enough to tell him to play golf, to instruct him to purchase a set of clubs and put himself into the hands of a skillful professional. His soul must be fortified by an explanation of the disappointments, irritations and depressions of the game at the same time setting before his mind the joy, beatitude and rejuvenation which follow in its train. For such an one it is a relaxation, a relief and an upbuilder of character, mind and body, an Antaeus-like contact with revivifying Mother Earth.

### Carnegie Fund Finds Economic Institute

**A**N IMPORTANT development and one which will make for stability and breadth of research is the establishment in Washington of an Institute of Economics. Financed by funds from the Carnegie Corporation, a paid staff of expert investigators, in cooperation with other economic bodies of recognized standing and with other institutions, will develop those fundamental economic facts which so closely concern the industrial life of individuals and nations. The first board of trustees includes Dr. Arthur T. Hadley, president emeritus of Yale University;

A. Lawrence Lowell, president of Harvard; Dr. Charles D. Walcott, of the Smithsonian Institution; Dr. Edwin A. Alderman, president of the University of Virginia; Dr. David Kinley, president of the University of Illinois; Paul Warburg, former member of the Federal Reserve Board; John Barton Payne, chairman of the Central Committee, American Red Cross; Robert S. Brookings, St. Louis; Charles L. Hutchinson, Chicago; David F. Houston, James J. Storrow, Boston; Bolton Smith, Memphis; Whiteford R. Cole, Nashville; Samuel Mather, Cleveland, and George Sutherland, Salt Lake City.

By means of bulletins and pamphlets the information collected by the Institute will be made available to leaders in political, educational, business, and social fields. One of the most hopeful signs of the times is the manner in which esoteric knowledge is being put to work in practical affairs. New standards of achievement will evolve with the complete reciprocity between economic and scientific fields. Particularly wholesome is it for those enthusiasts who think that social ills are due to one cause and will yield to corrective effort in a single direction to realize that welfare work, medical and social, is fundamentally a field of applied economics. Work will become more effectual and medical and health workers will be more in command of themselves and the situation as they become open minded students of the economic laws which control the expression of social life.

---

**T**HE acceptance of the Sheppard-Towner Maternity Act without delay by thirty-six states would be sufficient answer to those who have been trying to raise a "hue and cry" against what they imitatively call paternalism. An unbiased intelligence accepts this measure without question. It merely stimulates the states by Federal grants to engage in a program of education for maternity and infant care. It provides Federal grants to the states—a policy as old as this nation. It leaves the states free to accept or reject. It does not provide for Federal control; it merely gives Federal aid and counsel to the states for a national purpose.

---

**T**HE study of heart disease will receive added impetus from the most unique clinic in the world established recently by Sir James MacKenzie, eminent heart specialist in which every adult citizen of St. Andrews, Scotland, will be examined monthly. With such a controlled field of research, findings will doubtless be of value in combating the ever-growing menace of heart disease.

## Feeble-Minded Women in New York Industries

A Successful Experiment by Which Dependent,  
Subnormal Girls Were Rendered Self-Supporting

By EDITH HILLES, DIVISION OF WOMEN IN INDUSTRY, NEW YORK DEPARTMENT OF LABOR, NEW YORK CITY.

ACCORDING to figures collected by Dr. H. H. Goddard, there were in 1915 between 300,000 and 400,000 feeble-minded persons in the United States—at least 3 per cent of the total population. Less than one-third of these feeble-minded persons were being cared for in institutions. The remainder lived at home and were free to take part in the life of their community.

The dividing line between the feeble-minded and the normal person is indeed a shadowy one. Our standards change, our tests vary. Joseph Choate is reported as having once said, "the trouble with the feeble-minded is that there are so many of us."

The actual number of feeble-minded persons in the United States is unknown and it is probably much larger than popular estimates dare to place it. While there is a growing realization of the necessity for the segregation of feeble-minded persons and their custodial care, on the one hand, there is also a growing realization that these feeble-minded persons can never be adequately cared for until there is a definite policy established looking toward their self-support.

In connection with such a policy, New York State since September, 1917, has been trying out Industrial Colonies of moron workers.

Agricultural colonies for men, and a few for women, are coming to be more or less common types of experiment, but Industrial Colonies have not been tried to any extent.

*A greater knowledge of the way the human being in the factory works, and a wider study of the requirements of modern industry should develop a place where the mentally handicapped worker can maintain a useful industrial life.*

*Selection in such cases becomes synonymous with adaptation. Supplemented by right living conditions and such supervision as the case may require, useful and remunerative work should furnish the necessary foundation of stability in health and character.*

Domestic colonies have also been tried where a group of girls were housed in a town under the supervision of a matron and were available for domestic work at day, half-day or hourly rates. In December, 1919, the Central Labor Union in one of the cities where an industrial colony of feeble-minded girls had been established, with the girls working in a knitting mill, requested the New York State Department of Labor to make an investigation of the employment of these girls, inasmuch as the Central Labor body felt that the "employment of sub-normal girls has a tendency to undercut and underbid the normal girls, and to pull down the whole standard of labor."

Such study gives rise to many complications and the consideration of fundamental policies regarding the place of the high grade morons in the community. The cost of custodial or supervisory care would be so much as to make adequate state appropriations utterly impossible, and the custodial home in New York has since 1914 cared for the moron type of feeble-minded in colonies fifteen to twenty near the Parent Institution, in an effort to work out a scheme whereby this type of feeble-minded person could be made self-supporting and could approach becoming a normal part of the community.

The introduction of these sub-normal girls into Industry must be scrutinized from several points of view:

(1) That of the welfare of the girls themselves for whom it may be said that the experiment promises much. They are freed from the rigidity of institutional life, given regular, and, as far as is known, congenial occupation, and provided with the opportunity of forming social contacts.

(2) That of their fellow workers, who for the present purpose may be considered normal. The employment of the feeble-minded in private industry will tend to add increasingly to the inert and uncomplaining group who accept exploitation without question.

(3) That of the public at large which for its own protection is at present pledged to the extinction of the moron type. It is, therefore, to their advantage that as many as pos-

sible of this type be properly supervised.

The Superintendent of the Custodial Home in question, is, of course, primarily interested from the first point of view. As long as there are girls in the institution who can perform unskilled work in industry, and as long as industry is willing to engage them for this unskilled work, why should such an experiment not be tried? The work shop must, of course, have hygienic conditions. The payment must be on the same basis as that of normal workers doing the same work. The wage need not be high and, while an endeavor should be made to secure a wage that would permit the girl to live in the Colony House independent of aid from the Parent Institution, this wage might easily be beneath what a girl living by herself would need.

#### Attempt at Normal Environment

In the case of a strike, the Industrial Colony girls suspend work. This was agreed upon when the experiment was first planned, and such action was taken in May, 1920, when a strike occurred at one of the mills.

The point of view of the Superintendent of this home is that faulty environment contributes most of the trouble of a feeble-minded person. Proper training, good environment, and some supervision will very often remove the dangerous or bad characteristics so often at one with the feeble-minded. Colonies are viewed as stepping stones from the institution to parole and ultimate release. Parole may extend to a period of five years; while marriage is not "encouraged," release means that a girl will probably marry and have children. There is a plan to make a study at some time of the mentality of these children, but this study has not yet been begun.

In bearing out his theory, the Superintendent cites a study of the regeneration of the Jukes who were removed to new environments and who married into other families, as showing the treatment necessary in dealing with the feeble-minded. He also cites a study in Cincinnati of the success of pupils who formerly had been in the special classes in the public schools for backward and mentally deficient children.

"The feeble-minded recruits to this colony are chosen by a staff of doctors at the Custodial Institution. After training or observation, they are sent to the colony and tried on various processes in the mills until one is found at which they can work most

satisfactorily and efficiently. The processes at which these girls are employed vary, the job being adjusted, insofar as it is possible, to the special type of girl, but a point is usually reached beyond which they cannot go. Some stop at simple hand operations of carrying or cutting threads; others go on to the simple machine operations."

From the point of view of the feeble-minded girls, it may be assumed that such experiments as these colonies represent are extremely beneficial in that they enable girls to live as nearly as possible in normal life. As compared with the older custodial system, the advantages of such a plan are many: supervision presumably remains the same, but the individuals have a more normal environment and being engaged in work which is suited to their ability, a large percentage are separated from lives of crime and immorality and are made happy, industrious, and useful. In the meantime, the rooms vacated by them in an institution are made available to the more defective and, finally, insofar as each colony is self-supporting, the cost to the State for the care of the feeble-minded can be reduced and a given appropriation can, therefore, be made to cover a larger percentage of the estimated thirty thousand defectives in New York State.

It is claimed that during the last few years, the type of feeble-minded applying for institutional care has changed. "Whereas ten years ago 80 per cent were idiots and imbeciles and only 20 per cent borderline cases or morons, now only 20 per cent are of the idiot and imbecile class and 80 per cent morons or borderline cases."<sup>1</sup>

The Superintendent interviewed, states that this apparent increase of high grade types of mental defectives is due to the development and increasing complexity of the processes of machine production, which calling for a more and more highly organized type of operator, eliminates as unfit for use at complex machine or hand processes groups of persons who in another phase of industrial development were happily and industriously adjusted to their environment.<sup>2</sup> As Binet has said, "a French peasant may be normal in a rural community but feeble-minded in Paris." If this idea is followed to its logical conclu-

sion, the assertion can be made that inasmuch as common hand labor demands a lower degree of intelligence, the moron and none but the moron should perform what there is left of it. Such an assertion would amount to a proposal for placing the moron in the community in living and working units, for the purpose of substituting his common hand labor for that of workers otherwise and formerly considered normal. It would amount to committing unskilled work to persons of unredeemably low intelligence; the gradual adoption of a social policy which would recommend the retention of such in society because of their docility in the performance of stupid or routine tasks.

By nature the moron is happiest when provided with agreeable and monotonous work, and, given simple food and simple lodgings, asks nothing more of his employers; having no conception of the use or value of money, he is not liable to make complaint on the score of low wages. The superintendent of one of the mills is quoted as saying, "even though this class of worker produces unevenly, I can dilute my working force to the extent of 30 per cent with them and still maintain production. They live near by, are well disciplined, never complain, and never strike."

These industrial experiments are being tried by the Knitting Mill Company operating eight plants. About two-thirds of the working force in these plants are women. The output is knitted underwear. The women workers are entirely unorganized, the wage rates are comparatively low and conditions are unstandardized. While the labor supply is apparently adequate it is unstable and in a constant state of flux. Labor unions always claim that they have had trouble with the knitting mills, though there has never been a large strike. At first, the introduction of feeble-minded women was resented very much by the normal workers, but the strong feeling has died down.

The feeble-minded girls live in a colony house which accommodates from fifteen to twenty-five. A matron is in charge of the house, and supposedly this matron or someone designated by her, accompanies the girls to and from work and during their hours of recreation. They have been known, however, to take walks and go to the movies alone. Supervision obviously presents practical difficulties. Recently two of the women ran away; one was a high grade girl about twenty years old, and the other

1. Interview with superintendent.

2. Goddard, H. H.: *Feeble-Mindedness, Its Causes and Cure*, p. 575.

3. Machine production has to a great extent displaced common hand labor. Home Custodial Asylum, *Twenty-Second Annual Report*, 1916, p. 54.

was the mother of six illegitimate children, several of whom were feeble-minded.

At different times members of the feeble-minded colony have been returned to the Asylum as unfitted for the work in the mills. This unfitness includes failures due to other than industrial disability, such as sickness, flirting, or boisterous behavior on the street and similar offenses.

Their wages are collected and from that their expenses are paid; each girl is given twenty-five cents a week for spending money, and fifty cents a week for the savings bank. According to the Twenty-second Annual Report of the Rome State Custodial Asylum, it required about one-third of the earnings of these girls to support the colony, including the cost of furnishings, rent, etc. The remainder of all money collected is placed in the bank for general expenses, clothing, and other necessities, and each girl is given some money from the general fund for all necessary or reasonable purposes. There has been an improvement in the ability of the colonies to spend their earnings carefully.

The girls are trained at the various processes by their forewomen, and the range of time necessary for training is not limited, because of the fluctuating interest and lack of will in the moron as a type.

In November 1920, a further investigation of the colonies at two of the mills was made by the Division of Women in Industry. At that time the largest mill employed 220 workers, 159 of whom were women. There were twenty-five feeble-minded girls. The superintendent said he did not see how the plant could run without these colony girls. The mill was suffering from the common depression. The colony had been prepared for thirty-five girls but ten of the

normal workers ranged from \$17 to \$20 a week, and for the colony workers from \$12 to \$15; the maximum wage for the normal workers was \$30, and for the colony workers was \$22. Most of the workers were on a piece work basis, and the rates were the same for the normal and for the feeble-minded. In the other mill the colony girls numbered twenty out of a total force of 120 women. The superintendent claimed that the colony

earned an average wage of \$3.75, and the latter \$2.30. In this case the efficiency quotient is 62 per cent.

In occupations in the institution, an average efficiency of 60 per cent has been shown by about ¾ per cent of the total number of inmates (130).

For a group of forty-eight women aged 16-41, efficiency quotients were obtained as follows (average wage of twenty normal women used as divisor):

	Number	Average wage	Efficiency quotient
Group 1. High grade imbeciles.....	6	\$1.02	46.0
Group 2. Low grade morons.....	20	1.32	55.9
Group 3. Middle grade morons.....	9	1.44	65.0
Group 4. High grade morons.....	7	1.59	72.0
Hysterical.....	6	1.05	47.7

girls were about seven-eighths as efficient as the normal girls and that some were quite as efficient. He was loath to increase the present number too much, however, for fear of giving the mill a bad name. The girls in this mill were at practically the same operations as in the other, and approximately the same experience was found in wages.

Since colony workers and normal workers are working at the same processes and are paid the same piece work rates, in many instances, a comparison of the productivity of the two groups would seem possible, but since no account is kept of absence, the payroll figures available are of no value for such a purpose. The only study of this sort which is known, is that by Mr. George Ordahl, who studied the efficiency of the moron workers in comparison to the normal workers in an experiment carried on by The Sonoma State Home in Eldridge, California, where a group of girls was sent to a cannery during the shortage of labor. The result of this study is shown in the following table:

It may be noted here that the daily wage increased from \$1.02 for high grade imbeciles to \$1.59 for high grade stable moron.

It is undoubtedly true that some way should be worked out whereby the dependent subnormal could be self-supporting, not only for his own sake but for the sake of the community of which he is a part. It is a grave question, however, whether the state should adopt a permanent policy of placing workers, known to be subnormal, in private industries to compete with a supposedly normal group.

### Rôle of Visual Fatigue in Industry

Fatigue of the retina and visual centers occurs more frequently than suspected, states E. Jackson in the *American Journal of Ophthalmology*. Fatigue of the retina and that of the intracranial neuron cannot be discriminated. Fatigue is attended by lowered visual acuity as is observed when eyes are being tested. Age, exposure to light, overuse of the eyes at a near point for long periods of time, and disease influence the changes in visual acuity. The condition is also closely associated with general nervous breakdown, neurasthenia, or asthenia. Strong contrasts are likely to be fatiguing to the eyes. This is of importance because the power of the eye depends on sharpness of contrasts.

girls were taken back to the institution for correction of one kind or another; these colony workers attended to the simpler tasks. Fourteen of them were working on machine processes, and eleven on hand processes. The foreman in charge of the finishing department said that on the whole the feeble-minded girls were about two-thirds as efficient as the normal. The average wage for the

From these figures the efficiency quotient is found to be 60 per cent (reached by dividing average wage of group by average wage of normal women).

Seven normal women were compared with seven moron women who were packing tomatoes in cans. The normal women worked fourteen days (average), and the moron women worked five days (average). The first

In its building program, Indianapolis school authorities are considering plans for a four class room fresh air school. Besides the four class rooms there will be large sleeping porches, a dining room, kitchen and other accessories.

	Average days worked	Average pails peeled	Lowest daily average	Lowest daily wage	Highest average wage	Average wage
20 normal women.....	8	86.8	21	\$1.38	\$2.64	\$2.20
36 moron girls.....	6	22.0	14	.84	1.80	1.32

# Industrial Anthrax in Pennsylvania

BY HENRY FIELD SMYTH, M.D., SCHOOL OF HYGIENE, UNIVERSITY OF PENNSYLVANIA, AND ELIZABETH BRICKER, M.D., MEDICAL INSPECTOR, PENNSYLVANIA STATE DEPARTMENT OF LABOR AND INDUSTRY, PHILADELPHIA

THE question of the dangers of anthrax infection in industry from the handling of hides and skins, wool and hair, is one of increasing importance in this country. The study of reports appearing from time to time in medical literature seems to indicate a growing menace in this respect, at least from the handling of hides, skins, and hair.

**Wool.**—Up to the present there seems to be little infected wool handled in the United States though that there must be some danger from that source is shown by the fact that the Bureau of Labor Statistics Bulletin No. 267<sup>1</sup> lists five fatalities from handling wool. No. 142 was foreman and wool sorter in a Philadelphia mill handling China wool at the time (1916), No. 7 was a wool sorter in Williamsport sorting only domestic wool (1910) and No. 218 was a laborer in Philadelphia (1917) carting wool trimmings from a wool pulling factory. Osborn<sup>2</sup> lists seven cases of anthrax in Massachusetts from 1917 to 1919 among wool handlers, one of them from domestic wool.

**Horsehair.**—At the request of the Pennsylvania State Department of Labor and Industry the authors of this paper have made rather exhaustive surveys of both the horsehair industry and the tanning industry in the state to determine the probable anthrax hazards therein, and the results of these surveys will be summed up in this paper. The survey of the horsehair dressing industry has already been reported upon,<sup>3-5</sup> It was conducted in the fall of 1920 and that of the tanneries during the summer and fall of 1921. The burden of the work of collecting and tabulating histories of anthrax cases was born mostly by Dr. Bricker, the plant surveys were made jointly, the samples for examination were collected mostly by Dr. Smyth, and Dr. Smyth in person carried out the laboratory investigations connected with both surveys.

Philadelphia is the center of horsehair dressing in this country although it is a minor industry here, much of the horsehair used in brush making and weaving being imported ready dressed. During this investigation there were visited twenty horsehair dressing shops and a few other places handling horsehair, such as hair-cloth weaving factories, hair curling

and brush making factories, and a hair and bristle reclaiming shop. Most of the hairdressing shops are small plants with from two to six workers, the proprietors usually dressing hair themselves. The shops, with a few exceptions were dirty and cluttered with horsehair, dust, and litter. Undressed hair is received in bundles or large bales and there was no provision for separate storage of washed and disinfected hair and suspected imported hair. Clipped hair is received from the United States and Canada and from many foreign countries, and some hair is received on dried tail stumps.

Hairdressing is entirely a hand process and much of the hair is dressed unwashed. The occupation of hackling is a very dirty one, dust samples taken with the Palmer apparatus showing up to 1,000,000 quarter unit particles (0.5-10 microns in diameter) per cubic foot of air. Much of the imported hair comes from countries where anthrax is prevalent, as South America, China, and Siberia. Though considerable of the imported hair comes in under Consular certificates as from districts free from anthrax, yet our experience in the examination of hair and also of skins and hides, as will be detailed later, leads us to feel that this offers little if any protection. We have isolated anthrax from certified hair and a number of times from certified skins and hides. Osborn<sup>2</sup> points out the impossibility of a consul or importer in all cases assuring himself of the fact of freedom from anthrax in a district or even of being sure of the source of bales offered for export.

Samples were taken from bales of hair in all shops visited but most of them were from domestic sources and a number of these had been washed. Sixteen samples in all of foreign unwashed hair were cultured and thirteen of dressed hair from China. Virulent anthrax was isolated from dressed China horsehair and anthrax-like organisms failing to produce typical lesions in guinea pigs were found in five other samples, one of them domestic hair. The dressed China hair is that principally used for making the cheap horsehair shaving brushes which have been responsible for so many cases of facial anthrax throughout the country in the last few years.

There are none of these brushes made in this state, we believe.

In this work, as in the tannery survey, the diagnosis of anthrax was made as follows: samples of solid material, as dust, hair, skins, etc., were covered with nutrient bouillon and incubated for twenty-four hours. Heated portions of culture were then injected into guinea pigs or agar plates were poured, characteristic colonies fished and guinea pigs then injected with pure cultures suspended in saline solution. Where liquid samples from tanneries were examined, if they contained substances likely to injure guinea pigs, they were plated out in agar as above. Samples containing no injurious chemicals were heated to kill off non-spore forming organisms and then injected subcutaneously into guinea pigs. Anthrax was diagnosed only when injected pigs died with typical lesions, cultures of anthrax were isolated from their heart blood and were passed in pure culture through second pigs, killing the same with typical lesions.

The Bureau of Animal Industry regulations permit the disinfection of uncertified imported hair by exposure to 200 degrees F. for fifteen minutes, which seems to a bacteriologist an absurdly inadequate provision. Tests were carried out on disinfection methods with the following results: 200 degrees F. for fifteen minutes produced little if any reduction in the number of anthrax spores on samples; 200 degrees F. for twenty-four hours killed all anthrax spores in every test tried. Washing hair in hot alkaline suds as recommended by the Bureau of Animal Industry killed or removed most of the anthrax spores and subsequent drying at 175 degrees F. for twenty-four hours made this method fairly safe except that it did not protect the washer. Autoclaving at 15 lbs. pressure for 30 minutes killed all anthrax spores.

Cyllin disinfection used generally in England until recently proved absolutely inefficient.

The Bureau of Labor Statistics Bulletin 267 lists three fatal cases of anthrax in Philadelphia among hair workers, two in 1912, (No. 38, a bristle comber working Siberian hair and No. 63, a haircloth maker, also handling Siberian hair) and one in 1916 (No. 141, a laborer in a

horsehair factory handling Argentine hair.) We have hearsay or unofficial reports of four more cases which we have been unable to verify. This is a very small number, but the number of workers is small and the bulk of the hair dressed is domestic hair which for the present can be considered as probably anthrax free, though we did recover one anthrax-like culture from domestic hair and have tabulated 102 anthrax deaths, not traceable to any contact with imported materials and unconnected with any tannery, woolen mill, or hair factory, in twenty-six states since 1910. Some of these may have been shaving brush infections, but a number gave a history of infection from livestock.

As a result of the above findings the Industrial Board of Pennsylvania adopted the following regulations:

(1) That all horsehair, as early as possible in the process of its manufacture, preferably before the bales are opened, or with the minimum amount of handling after the bales have been opened, be subjected to one of the following processes: (a) Subjection to dry heat at a temperature of 200 degrees F. for twenty-four hours. (b) Subjection to steam at fifteen pounds pressure for a period of two hours. (c) Boiling with the hair constantly covered with boiling water for three hours.

It was suggested that disinfection had best be carried out at a central disinfecting station as is being tried out in England at present.

*Hides and Skins.*—The tannery survey was naturally a much more extended one than that of the horsehair industry. At the time the survey was conducted only about two-thirds of the tanneries of the state were in operation, owing to business depression, but all except three of those that were running were visited and sampled. Of these three only one was of any considerable size, the other two operating only part time with a very few men.

The tanneries handling stock that is liable to contain anthrax may be classed in two main groups; those handling cattle hides, including buffalo, and those handling goat skins. Only three handle horse hide and this is all domestic stock. Six handle sheep skins but these are all received in salt and acid pickle. There were visited forty-seven tanneries receiving cattle hides and sixteen receiving goat skins.

In considering the anthrax risk in tanneries we considered as directly exposed only those who handled unlimed skins, since case histories and laboratory tests showed that there was little if any risk in handling limed dehaired stock. The few cases on record of employees in other departments of the tannery handling tanned stock we feel are probably accidental dust or contact infections from the untanned skin departments. Making this division we found that the tanneries visited and those now closed that gave histories of anthrax cases had a total of 13,339 employees

with 1,040 of them—or about 7.8 per cent—directly exposed to risk of infection. In cattle hide tanneries there were 7,458 employees with 614, over 8 per cent, exposed, and in goat skin tanneries 5,881 employees with 426 (over 7 per cent) exposed (Table I).

In or connected with these tanneries for the last 12 years we have succeeded in listing 123 cases of anthrax traceable to one or the other type of raw material (Table II). Of these cases about 21 per cent, or 26 cases, were fatal. Seventy-three cases with 16 fatalities, about 21 per cent, were from cattle hides and 50 with 10 fatalities, 20 per cent, were from goat skins. In addition to fatalities, we have tabulated time lost by non-fatal cases, and find that the 82 cases for which we have been able to obtain this data lost an average of 38.36 days per case. This would make 3,759 days lost in twelve years by the 98 non-fatal cases, or an average of 313 days per year. On this basis we can estimate that one tannery with 16 cases of anthrax lost 613 days in the eleven years and a tannery with 6 cases in one year lost 230 days in that year (Table III).

TABLE III.—TIME LOST BY NONFATAL CASES OF ANTHRAX

Total nonfatal cases in 12 years .....	98 cases
Average time lost (reports of 82 cases)....	38.36 days
Total estimated time lost .....	3,759.28 days
Average estimated time lost per year.....	313.27 days
Greatest estimated loss in 1 year (22 cases)...	843.9+ days
Greatest estimated time lost in any tannery (16 cases).....	613+ days
Greatest estimated time lost in any tannery in any one year (6 cases) .....	230+ days

In addition to the regular tannery employees infected there are several freight handlers and longshoremen on our list and seven carpenters or repair men infected from repairing or tearing down old soak vats or, in one case, the drain from soak vats. Two wives of tannery employees were infected, one from washing and the other from mending her husband's clothes.

To show the incidence of infection among tannery employees we have studied the reports for the years 1916 to 1920 inclusive. Before 1916 we feel sure our records are far from complete and 1921 has been such a poor year industrially and so many tanneries have been closed or on part time that we have thought best to omit it. This study (Table IV) shows for the five years an infection

TABLE IV.—ANTHRAX MORBIDITY IN TANNING INDUSTRY IN PENN., 1916-1920

Year	Cattle hide tanneries		Goat skin tanneries

rate of 1.9 per cent per year among exposed cattle hide tanners and 1.5 per cent per year among exposed goat skin tanners, or in the five years a total of 8.7 per cent of those directly exposed who contracted anthrax. Histories of one or more anthrax cases were obtained from 23, or 40 per cent, of the cattle hide tanneries and from 8, or 42 per cent, of the goat skin tanneries.

In all the tanneries visited samples were taken and examined in the laboratory by the method previously mentioned. As a result of these examinations the following positive results were obtained (Table V). In cattle hide tanneries four positive anthrax cultures were obtained from 155 samples taken. Two of these were from one tannery soaking certified South American green-salted packer hides at the time. They had received dry hides two months previously and the anthrax may have come from them, either having remained in the vats from former soakings or infecting the new hides as dust from the stock room. One culture was from green-salted non-packer certified hides from South America soaking in sulfide solution. This tannery handles no non-certified hides. The fourth culture was from a so-called disinfectant soak of 1-1,000 mercuric chlorid in which some Indian water-buffalo hides had been soaking for twenty-four hours. This will be referred to again. These tests showed anthrax in only 2.5 per cent of the samples taken and in 6.38 per cent of the cattle hide tanneries visited.

At present most of the cattle hides being tanned in Pennsylvania are from packer killed cattle, either domestic or South American. These beef cattle are not apt to have anthrax when killed. Formerly many non-packer hides were imported and no

doubt when business conditions return to normal many more will be. Most of these tanneries are packer controlled, and at present the packers produce almost enough hides to supply them all. These packer hides are received green-salted in a moist condition, tied individually into square bundles with the hair side in. They give rise to no dust in unpacking or handling. In 1921 three tanneries had received dry hides, in 1920 two more, in 1919 two more, and in 1918 five more, or 12 in all, and in many cases these dry hides were proved to be directly responsible for cases of anthrax, as in the one case in May 1921. Two cases in 1920 were directly traceable to handling green-salted hides, however.

These cattle hides are tied end to end in long ropes and soaked twenty-four to forty-eight hours in plain water and then transferred to strong lime suspensions, 20 per cent or over,

to prepare for dehairing. They remain from four to twenty-four hours in a single water soak and often in running water, and are then soaked in lime four days or more before dehairing. They are transferred from vat to vat over reels without untying and with a minimum of handling and the vats are cleaned out thoroughly and at times whitewashed after each soak. This all tends to lessen the risk of anthrax in this branch of the industry, but a record of 73 cases in twelve years, with no year without a case, and with a mortality of over 21 per cent shows that the risk is still there.

Conditions in goat skin tanneries are somewhat different and tend to increase the anthrax hazard among employees. Some skins are received green-salted, packed in casks, but the majority are dry and packed in large close bales. Over 99 per cent of the goat skins are imported, mostly from countries where anthrax is prevalent, and culture tests show that many skins imported as certified contain virulent anthrax. These dry skins are loosened from the bales, weighed on small scales, and put to soak by hand. They soak 24 to 36 hours in single vats, are then pulled out by hand, placed by hand in tumbling mills to soften, trimmed over a beam, and placed in limes by hand. The dry skins produce much dust and are a source of skin wounds to handlers. In pulling soak vats the laborer must get into the drained vat and his clothing becomes soaked with water, often containing anthrax. Most of the anthrax cultures obtained from these tanneries were obtained from test tube samples dipped from the surface

of these vats or from the liquor from tumbling mills.

In goat skin tanneries the following culture results were obtained (Table V).

Thirteen dust samples were taken in six tanneries. Four positive anthrax cultures were obtained in samples from three tanneries. This gave 30 per cent positive samples and anthrax in dust 50 per cent of the tanneries so sampled. Two of these tanneries had no uncertified skins on hand at the time.

One hundred thirty-five plain soak samples, including samples from mill drums, taken in eleven goat skin tanneries gave 32 anthrax positive, 23 per cent, in six tanneries, or 54 per cent. This gave anthrax positives in six out of the eleven goat skin tanneries sampled, or 54 per cent. The majority of these cultures came from soaks or dust from certified, supposedly anthrax-free stock. Samples were not taken in five tanneries as they had no raw skins on hand at the time.

The problem of disinfection of hides and skins for anthrax is a most difficult one and one that is as yet far from complete solution. Anthrax spores are highly resistant and on the hides they are protected by matted hair, dirt, and blood. Any agent that will reach and kill the spores is apt so to alter the hide that it can no longer be tanned. We have found several gaseous agents which will kill anthrax but they disintegrate or toughen the skin so as to ruin it for tanning.

The Bureau of Animal Industry regulations require that all hides or skins that are imported without consular certificates shall be shipped to the tannery in sealed cars, opened under supervision of a department inspector, and disinfected by an approved method. The method of disinfection used by practically all cattle hide tanners is to soak twenty-four hours or more in a 1-1000 mercuric chlorid solution. The usual proportion of hide to solution is 1.250 lbs. in 1000 gallons. Laboratory tests show that with this ratio the mercuric chlorid all combines with the hide and at the end of one hour there is no free  $HgCl_2$  in solution. This indicates the worthlessness of the method and it was shown practically by the isolation, as previously mentioned, of virulent anthrax from a vat containing 1-1000  $HgCl_2$  solution in which a batch of India water-buffalo hides had been soaking for 24 hours.

The Schattenfroh method of disinfection by soaking in a solution of 10 per cent NaCl and 3 per cent HCl has been proved to be very efficient in

killing anthrax on hides, as shown in tests previously reported by one of us<sup>1</sup> but Pennsylvania tanners have apparently succeeded in convincing the Bureau of Animal Industry authorities that they cannot make glazed kid from skins so treated. However we have been informed that it is used routinely for skins for upper leather in Massachusetts and we know of at least one Philadelphia tanner who was prepared to use it before the Bureau of Animal Industry allowed them to use lime. The present regulations call for a twelve hour soak in 15 pounds of either burnt lime or hydrated lime per one hundred gallons of water. They state that this approximates the 5 per cent CaO mixture formerly required. A most liberal estimate only shows that if the limes were 100 per cent CaO—which they never are—the concentration would be a little over 1.8 per cent, rather a crude approximation to 5. That the average soaks are much less than this is evident when we realize that commercial limes do not average more than 75 per cent CaO. To test the efficiency of calcium oxide disinfection series of laboratory tests were carried out with different strengths of lime suspensions made from burnt lime and from hydrated lime with the following results. Twenty per cent CaO from burnt lime or hydrated lime killed all anthrax spores on skin samples in 8 to 10 days. Ten and fifteen per cent CaO seemed to be equally efficient. Five per cent CaO from burnt lime or hydrated lime sterilized the skin samples in ten to seventeen days. 1.875 per cent CaO from burnt lime killed anthrax on skins in ten to twenty-one days, and the same strength from hydrated lime failed to kill all anthrax in twenty-one days. Tests with anthrax spores in suspension showed that the 5 per cent suspension from burnt lime killed all spores in four to seven days, with a 70-80 per cent reduction in three days. Of these four suspensions, the 1.875 per cent suspension from hydrated lime was the only one that did not kill all spores in eleven days. These tests indicate that the Bureau of Animal Industry regulations as regards hide and skin disinfection are woefully inadequate. Several goat skin tanners soak all uncertain skins in a 10 per cent lime suspension for twenty-four to thirty-six hours. While this will not insure sterilization, it will undoubtedly materially lessen the risk of infection by destroying a great proportion of the spores.

It was thought that possibly a long

contact with lime might destroy the virulence of spores before it killed them, but this is not always the case as a culture obtained from a 10 day soak in 5 per cent CaO from burnt lime proved to be virulent for a guinea pig. All of the comparative tests with lime showed a somewhat more rapid and more certain action where burnt lime was used rather than hydrated lime.

To test the protective value of whitewashing vats after soaks, bits of wood and of carborundum were sterilized, dipped in anthrax spore suspension, and then in strong lime suspension and then dried over night at room temperature. Cultures from these samples, when compared with unlimed controls showed a considerable reduction in numbers of anthrax colonies developing but not a complete sterilization. A practical test in one tannery showed that a vat presumably seeded with anthrax and giving three out of four positive cultures at two day intervals did not again give a positive culture after whitewashing until the fourth trial on the eighth day. This may have been from anthrax freshly introduced in a new batch of skins.

The tannery survey may be summed up as follows:

The survey included forty-seven tanneries handling cattle hides and sixteen handling goat skins, as well as some others handling non-infective materials.

The survey consisted of field surveys of tanneries, collection of samples and laboratory examination of the same for anthrax; also the collection and tabulation of histories of anthrax cases chargeable to the tanneries, and some laboratory experiments bearing on the efficiency of the methods of disinfection recommended by the Bureau of Animal Industry and employed by the tanners.

Anthrax cultures were isolated from vats in 6 per cent of the cattle hide tanneries, three times from certified stock and once from disinfected non-certified stock.

Anthrax was isolated from 54 per cent of the goat skin tanneries; 4 times from dust (30 per cent of samples), 24 times of soap vats (19.6 per cent of samples), and 8 times from tumbling mills (61 per cent of samples). In all, 314 samples were taken and cultured for anthrax. The great majority of the isolations were from certified stock.

All diagnoses of anthrax cultures were based on animal inoculation tests in series.

Laboratory tests showed the in-

efficiency of HgCl<sub>2</sub> disinfection as did one field test.

Laboratory tests showed the inefficiency of disinfection of skins with CaO, fifteen pounds to the one hundred gallons of water, or even in 5 per cent suspension.

These tests showed that stronger lime soaks, 10 to 20 per cent, will kill most anthrax spores provided the exposure is for, at least one week.

Laboratory tests and field tests showed the probable partial efficiency of lime washing as a means of destroying anthrax in vats.

Anthrax cases were reported from 9 out of 19 (50 per cent) goat skin tanneries (5 not now<sup>o</sup> in operation), and from 23 out of 57, 40 per cent, cattle hide tanneries (10 not now in operation). In the former there has not been a year since 1916 without at least three cases and in this time there have been six fatalities. In the cattle hide tanneries there has not been an anthrax free year since 1910 and but three years without one or more fatalities.

The comparatively few fatalities among goat skin tanners is probably due to early diagnosis and accessibility to hospitals.

In the years from 1916 to 1920 inclusive 9.6+ per cent of employees in cattle hide tanneries who were directly exposed to risk of infection contracted anthrax and 7.5+ per cent of the same in goat skin tanneries, an average of 1.7+ per cent morbidity per year in the combined groups.

During the 12 year period 1910-1921 cases among cattle hide tanners showed a mortality rate of 21+ per cent and among goat skin tanners 20+ per cent, or 21 per cent for the combined industries.

Non-fatal cases were responsible for an average time loss per case of 38.36 days. This totals 3,759 days for the 98 non-fatal cases in twelve years or an average of 313 days per year for non-fatal cases. One tannery with 6 cases in one year lost 230 days.

### Recommendations

Based on the findings of the above survey we would make the following suggestions.

It is difficult to suggest recommendations for disinfections of hides and skins without criticism of the present Bureau of Animal Industry rulings. The tanners as a class endeavor to follow these rulings whether they have faith in their efficiency or not. The Bureau of Animal Industry itself realizes that they fail to give complete protection. Dr. Mohler states that "it is a practical impossibility

so to handle imported hides and skins as to eliminate all danger to tannery workers. This danger could only be completely eliminated by bringing in to this country non-infected skins. It may be said, therefore, that the regulations covering the handling of uncertified imported skins serve to lessen the danger of anthrax infection but that they do not absolutely prevent it." This is undoubtedly correct, but in our opinion the regulations might be improved upon.

We would suggest enforcement of disinfection of all imported goat skins except those from western Europe, regardless of certification, and the disinfection of all imported cattle hides that are not packer hides.

The use of bichlorid of mercury should be discontinued.

Disinfection of hides and skins should be by the Schattenfroh salt and hydrochloric acid method or by 10 per cent CaO lime suspension for twenty-four to thirty-six hours, the lime to be freshly slacked in the vat. Hydrated lime should not be used for this purpose. It must be realized that this does not give complete protection and these skins must still be handled with care. Glazed kid manufacturers, in Philadelphia, object to using the Schattenfroh method, claiming that it prevents the making of good kid, but we know of at least one tannery that was prepared to use it when they thought that the Bureau of Animal Industry was going to insist on its use. We would suggest a conference with the Massachusetts authorities as to its practical application in that state.

We would suggest the lime washing of soak vats, tumbling mills, and of the floors around vats and under mills once a week at the close of the day's work in that department. This would lessen risk of permanent infection of this department with anthrax. To prevent accidental infection of repair men, etc., as has happened in at least three tanneries we would insist that no repair men work on any surface that has not been so lime washed within the last 24 to 36 hours.

No dry sweeping should be permitted in tannery stock rooms. Floors should be swept up at the close of each day's work after a liberal sprinkling with one of the disinfecting solutions permitted by the Bureau of Animal Industry regulations, or better, should be washed up with the same. All rooms where raw goat skin stock is handled should be considered possibly infected and all rooms where imported non-packer hides are handled should also be so considered.

For the sanitation of workshops we recommend provisions similar to those suggestions given in Massachusetts Board of Labor and Industries Industrial Bulletin No. 6, quoted in Appendix A, page 163, United States Bureau of Labor Statistics Bulletin No. 267.

We would emphasize the value of medical service to tannery employees, the education of the employee in the methods of minimizing his anthrax risk; as, care of all skin wounds or eruptions however trivial, and immediate surgical treatment of all breaks in the skin.

We would insist upon adequate wash rooms for exposed employees with shower baths and dressing rooms so arranged as to keep working clothes and street clothes separate. Working clothes should be disinfected by formalin before being laundered. It would be best to have the company responsible for disinfection and laundering.

If hand disinfection basins are used the employees should be instructed to scrub the hands vigorously with soap and water and then to rinse them before using any hand disinfectant. Otherwise the solutions soon become so full of organic matter as to use up all of the disinfectant present.

No satisfactory hand disinfectant has been suggested as yet.

Two phases of anthrax protection are being studied further by one of us and a collaborator from the Department of Chemistry of the University of Pennsylvania—one the subject of hand disinfection, and the other a search for a more suitable efficient means of disinfecting hides and skins before soaking, or possibly before taking out of the bale.

Considering the proved prevalence of anthrax in imported non-packer material and the known infectiousness of the organism it is rather remarkable that there has not been a greater incidence of infection among tanners. This can only be attributable to the watchfulness of the majority of the tanners and their prompt attention to all skin wounds among workers in wet processes. The low mortality, especially among the goat skin handlers is due to early diagnosis and prompt specific treatment.

We would emphasize the importance of early reporting of all anthrax cases.

# Cooperation Between Employers and Employees

## Effective Team Work Grows Out of Mutual Interest and Mutual Understanding

BY OCTAVIUS M. SPENCER, M.D., WASHINGTON, D. C.

PLANT managers are usually very familiar with their plant conditions. Some admit that conditions could be improved; others say that they are the same conditions that have existed for a number of years, and are therefore good enough; a few frankly make the statement that if the workmen do not like the conditions, they can seek employment elsewhere. This is particularly true at a time like the present, when labor is plentiful. A few employers are interested in their workers, some are lukewarm towards them, others give them no consideration. In a few cases, for display or show, some install modern personal service facilities, showy dispensaries, or dental clinics. Others, because competitors make improvements of this nature think that it is necessary to follow suit. A great many changes are made because of state compensation and sanitary laws. In only a few cases are these facilities installed because of the employer's human interest in the workers and his desire to educate them towards better health conditions, which will in turn act as bread cast upon the waters. However, there are times when the employer, whatever may be his reason for installing personal service facilities, a dispensary, and modern plant methods, is disappointed and cannot understand why these improvements do not prove a success. The answer to this is not hard to find: the failure is due to lack of cooperation and lack of education of both employer and employees. Lack of education on the part of the management is also complicated in many cases by a failure on the part of the management to understand the workmen, while on the other hand the workmen do not understand the object of the management in making these changes, since no explanation is offered them as to the benefits which they will receive.

Operator and operatives need to get rid of their present suspicion and their mercenary ideas, and to assume a simple, unselfish, and mutually beneficial attitude, each admitting to the other that there can be no success without cooperation. This will affect

*It is admitted that no real study of existing conditions in any industry can be made, and much less can an effectual health program be applied, without frank support on the part of the workman. Emphasis is now made that the same whole-hearted, sympathetic support is necessary on the part of the management.*

*Manager and employee as the chief beneficiaries in industrial hygiene should be equally interested. Education to this end, however, may require the broadest interpretation, from teaching the foreigner the A. B. C's, to educating the manager to a proper evaluation of scientific management in industry.*

production, maintenance, cost, labor turnover, absenteeism, sickness, and the success or failure of welfare work and personal service facilities.

Usually investigations or plant surveys are made either at the request of the plant management or at the request of the employees, and back of the request of either there may be numerous motives, such as desire to increase production, to decrease cost, to eliminate a hazard, to cut down insurance premiums, to increase or decrease compensation. Aside from the clothing trades, can you mention any plant survey or investigation in which plant management and workers have joined forces and requested the survey for their mutual benefit?

Many studies have been published on motion, fatigue, monotony, posture, output and many other conditions affecting modern plant conditions; but the improvements suggested by such studies depend upon the degree of cooperation between employer and employee in the use of the facilities, the regulations, so involved.

The worker controls and governs to a great extent the tenor of all studies and investigations of the nature mentioned above and makes a success or a failure of the conclusions, provi-

sions, and installations following such studies. As the employee is here almost all-powerful, as upon him depend modern industry and the success of modern industrial improvements, it would be well to devote more time to his interest and to gain his cooperation and his confidence. If this is undertaken in an intelligent manner in an endeavor to show the worker how and whereby he will profit, both in health and in money, we may hope for better success with plant hygiene, and at the same time the interest of the plant management will become more humane and less mercenary.

No doubt there are many who do not agree with me in this; but since the average worker spends only one-third of his time in the plant and the remainder as he will, how is it possible definitely to control his actions as to the preservation of his health, the elimination of fatigue, etc., while he is away from the plant, unless he will cooperate?

Where is the dividing line between plant conditions and home conditions, as to effect on the sickness rate, the rate of absenteeism, and the rate of labor turnover? All conditions in the plant, favorable and unfavorable, apply to only one-third of the worker's time, and conclusions based upon one-third of an individual's time can not be an accurate factor in producing the sickness rate, rate of absenteeism, rate of labor turnover and physical defects found in the workers. Likewise, it is impossible to tell just how many of the physical defects observed in a given case are caused by conditions of work, and how many are caused by the individual indiscretion. In saloon days many trades were considered hazardous. Insurance companies refused to insure the workmen in the glass industry, for example. Yet today insurance companies insure most of the glass workers, for it has been found that the personal habits of the worker and not the trade caused the high mortality rate.

In the sickness or dispensary records of the plant how many cases of headache, eyestrain, constipation, etc., should be charged to illumination, ventilation, humidity, seating facilities,

and other plant conditions, and how much should be charged to the home conditions or conditions outside the plant,—such as extra work, poor ventilation and illumination of homes, indiscretion in diet, too many picnics, late hours, poor cooking, and other unhygienic home conditions?

### Causes of Absenteeism

As to absenteeism, how much is due to the plant conditions and how much to life outside the plant, it is impossible to say, but many home conditions that produce absenteeism in the plant could be changed by education of the workers and their families. If the wife or husband were familiar with a dietary system and knew how to discriminate properly as to the foods that should be eaten during various seasons of the year, and if the feeding of infants and younger members of the family were properly regulated, many of the digestive disturbances and summer diarrheas would be obliterated, thus cutting down absenteeism due to sickness of the worker himself, or to sickness of members of his family which render it necessary for him to remain away from the plant. Why not educate the men and help them prevent sickness in the family? Such education can be accomplished through visiting nurses, through health lectures, and through the cooperation of the state or city health authorities in the town or locality in which the workmen live. While this education and home work may seem to be without the field of industrial hygiene and sanitation and within that of sociological work, yet the activities, the environment, and the conditions and their effects of the two-thirds of his time spent away from the plant all have a direct bearing on the worker's health and physical condition in the other third of his time when he is in the plant.

In the plant the worker is under a certain additional amount of nervous strain, under a certain amount of tension, and is therefore more likely to be sensitive to impairment of his normal functions than he is when at home or elsewhere, under no particular strain. However, in some cases home conditions may cause these conditions to prevail there; if they do, eventually the worker will break down.

It is far better to educate and to gain the cooperation of the employees than it is to force their half-hearted or partial cooperation by threat of fines or dismissal. American employees refuse to be driven, and if

they are driven, whenever they get a chance, they will kick over the traces. Show them how by cooperation or by team work they can succeed or profit, and they will do their utmost.

### Must Arouse the Interest

It is human nature to be careless and unobservant, and the only way to prevent carelessness and lack of observation is by impressing an error so on the offender that he will not again forget or become careless.

Just think for a moment, of the times you have visited a plant where modern facilities of all types and forms are installed, and what have you found? The walls everywhere placarded with signs for the workers: "If you do this or that, you will be fined or discharged, you will be suspended, etc." Why not educate the worker and have him fully understand the problem? If Bill Smith expectorates on the floor, uses a common drinking cup, leaves an elevator shaft open, does not sit properly in a chair, or does anything else that is contrary to the best teaching, do not fine him, discharge him, or suspend him; but make what Bill did, the subject of a short, clear instructive lecture on what might happen as a result of Bill's action. The result will be that everybody in the plant will be on the lookout for violations of the sanitary and safety regulations and the episode will tend to make all more careful in order to avoid embarrassment similar to that of Bill Smith.

Gain the cooperation of the workers and have everyone of them become a sanitary or plant inspector, and you will not have them doing all they can to hide bad plant conditions or undesirable acts of their fellow workers. If the workers are in cooperation they will aid in the carrying out of regulations and will work for the general success of the plant and for the benefit of their individual health as well.

Americans will cooperate and pull together when they are properly handled or approached, but they are the hardest people on earth to be driven. Therefore, is it not best to begin at the top, to get the plant management to put the problem up to the workers, to put all cards on the table and show the workers how the installation of modern welfare facilities and modern methods of production will help them, and thereby remove from their minds the suspicion that all this is for show, or for increasing their output at the same

wages, and that the safety-first work is because of interest in the workmen and not merely to save the plant doctors' bills and insurance? See that the officials of the plant are educated in these matters and that they in turn aid in the education of the workers, and in this manner we can have everyone in an industry cooperate from the president of the corporation down to the poorest worker.

Trust your employees as human beings. They are sensitive and intelligent, subject to certain human faults and shortcomings, but nevertheless capable of seeing and observing conditions and surroundings. They are your best bet to make your plant a success. Treat them as human, tell them why this or that is done, why they should not do this or that. Educate them and seek their aid and cooperation. Just remember that workers are human beings, and have homes, and loved ones, and are not mere tools.

### To the Employee

Don't consider the plant where you work as just a place to go and to remain in from one whistle to another, in order to receive so much money. Consider it a place where you have a chance to develop, where you can lay the foundation for your success in this world.

Don't condemn the plant management until you find out the plant policy and the reasons for doing things, nor the plant facilities until the facilities have proved unsuccessful.

Don't kick about things just because John kicks. Find out if things are as John says and see if they can be changed; maybe John is wrong, and maybe, by a little study of your own, you can prevent the spread of grumbling and dissatisfaction. A habit of grumbling and discontent is one of the easiest things to become afflicted with. Avoid it. Be sure you know the truth before following in line. As in the army, remember how when you joined the company or the squad, somebody said Sergeant So and So was a bully, a rough neck, and how you, too, considered him such, but never tried to find out if it were true; or if you did find out, you found the Sergeant a good fellow.

Take advantage of the personal welfare facilities offered, of the classes and lectures, of the amusements, of the modern equipment provided, and of the suggestions given for improving your home conditions. Study the rules, regulations and laws governing your work and learn for your-

self the wisdom of their enforcement.

Also be careful and considerate of your health and your family's health and don't blame the plant for some physical ailment of yours that may be

the result of your personal indiscretion when off duty. It isn't fair to raise Cain on Saturday night and Sunday, and to blame the plant for headache, constipation, and other ailments experienced on Monday.

So Mr. Employer and Mr. Employee: Stop, read, and think, before you condemn a suggestion, a method, or an installation, that is likely to prove an aid to you for efficiency, health, or welfare.

## Corrective Measures in Disabilities of the Back

By W. B. FISK, M. D., CHIEF SURGEON, INTERNATIONAL HARVESTER COMPANY, CHICAGO, ILLINOIS

MANY confusing questions arise in the course of the day's work of the industrial surgeon, questions which become more complex with the ever widening scope of industrial medicine. The man in general practice has only to determine the diseased condition to be dealt with and the method of its handling. Problems of this nature in industrial medical practice carry with them economic considerations of far reaching importance. In the matter of hernia, for instance, it has been an open question for years whether to regard it as traumatic in origin or as due to hereditary conditions. Disabilities arising from weakness of the back, so-called strain, lumbago, or sciatica present even greater difficulties. It happens almost daily that employees present themselves with the complaint that in doing certain work they were taken with sudden pain in the back. The physician must decide for the Industrial Accident Board whether such disabilities are to be considered as arising out of and in the course of employment, or whether the pre-existing condition would have induced pain whether the men were at work or not.

For several years I have been wrestling with this problem, and have made many efforts to obtain a solution, but it is only within the last ten months that I have felt that I was working along the right lines. The report on eleven patients which follows is to be considered in the light of a preliminary report. I am rather reluctant to lay much claim as to results because of the few patients which I have treated, but the very gratifying results obtained on these few patients, prompts me to submit the following:

It is not the purpose of this paper to deal extensively with the subject of arthritis, but rather to call attention to one condition which we have often seen in acute arthritis, and less often in chronic cases or in patients known to have a definite pathology. In the condition to which I wish to direct your attention there

is usually little, if any pathology that can be positively demonstrated by x-ray or otherwise. This statement is supported by clinical history as well as by x-ray pictures.

### Clinical Picture

These patients complain of pain in the region of the sacro-iliac joint either right or left, seldom both. In the eleven patients covered by this report the pain was localized about the left sacro-iliac seven times, about the right sacro-iliac three times, and over the fifth lumbar vertebra once. When a patient presents himself for examination he stands with the heel on the affected side slightly raised from the floor, the knee is flexed a few degrees, the hip thrown outward and backward, and the lumbar spine is thrown forward slightly flexing the spine on the pelvis. This position is assumed in order to relieve pressure on the painful area. The shoulders are thrown backward, thus increasing the dorsolumbar curvature in order to bring the center of gravity within the support. Many of the patients are unable to lie flat on the abdomen. The most comfortable position for these patients is on the back with the leg on the affected side sharply flexed at the thigh and knee. Forceful extension of the leg with the patient lying on his back usually increases the pain. Spasm of the lumbar muscle is usually present and is increased with any movement or position that increases the pain. The patient usually complains of pain before the characteristic deformity is noticed.

In two of the first eight patients of the series, the patient had pain for several months before deformity was noticed. To me it is very significant that these two patients developed their deformity while in bed. Each made the statement that they were able to stand erect when they went to bed, that they had severe pain in the night, and the next morning they were unable to stand erect.

The treatment has been the same in every case. It consisted in com-

plete relaxation under anesthesia and with the patient lying on his back with shoulders fixed a slow strong pull is made on the legs. The pull is steady and is equal to a lift of seventy-five to one hundred pounds. In making the pull, the ankles are grasped by the operator. I usually place one foot against the table in order to exert a strong pull, I then turn the patient on his abdomen and with my helper working on the opposite side I thrust my arm under the knee of the patient with the forearm hooked over the lower part of the thigh. My other hand rests on the sacro-iliac joint. The patient's thigh is then drawn downward and at the same time is over extended on the body while the sacro-iliac joint is pressed forward.

I never use fixation appliances of any kind after the stretching operation. One patient has had a recurrence of this deformity after a working period of six months.

### Case Reports

Mr. J.—aged 39, examined June 15, 1921. He gave a history of having had two attacks of arthritis—one fifteen years before which laid him up two weeks. A second attack came on March 15, 1921, and continued for three and one-half months. Patient has had typhoid fever and pneumonia. One night about June 1, 1921, while in bed, the pain became very severe in the lower part of the back. Next morning patient was unable to stand erect. Pain and mal-position had been present for two weeks prior to examination. I sent the patient to the hospital, put him to sleep with gas, and did the usual manipulations. The patient got off the table alone, stood erect and walked freely without pain. He left the hospital the following morning. He returned to work in one week and has had no pain to date (March 1, 1922). The x-ray shows no pathology.

Marie F.—This girl complained of pain for several months. On November 5, 1921 the pain was so severe that she had to have assistance in getting home. She went to bed and on the following morning was unable to stand erect. She remained in bed for one week. During the two weeks after her stay in bed she was up and

about the house. Her pain was extreme. She had a marked characteristic deformity. She was taken to St. Luke's Hospital, November 28, put to sleep, stretched, back manipulated and returned to bed. On December 1, four days after the stretching, I had her get out of bed, stand erect, over extend the lumbar spine and walk, all of which she did without pain. She returned to work in two weeks, but later claimed disability because of pain in the outer side of the calf and sole of the foot. She was not working March 1, 1922, although she is able to stand erect, bend forward and lie on her face or back without causing pain.

A. S.—age 23, strong, healthy girl. Gave no history of previous illness or injury. September 4, 1921, she slipped and fell down a short stairway. She was scarcely able to stand for two days. When in bed her most comfortable position was on her right side with her left thigh flexed on the body and leg sharply flexed on the thigh. I examined her September 6, 1921. She complained of severe pain over the left sacro-iliac joint. She was unable to lie on her face. In standing she assumed the characteristic deformity. The x-ray showed no pathology. She was taken to the hospital September 7, put to sleep with gas, stretched, and back manipulated. Five minutes after regaining consciousness she turned without assistance and lay flat on her back and then turned with face down. Neither position caused pain. She remained in the hospital four days, then went home. She returned to work in ten days and has had no pain since.

Wm. F.—Male, aged 22. Family history negative. Both parents living and well. Patient had scarlet fever thirteen years ago. No history of injury. Present disability began May 10, 1921. History of its onset is as follows: In January, 1921, while pushing a loaded truck, he slipped, both feet going from under him, allowing his back to over extend. He clung to the truck with both hands. No symptoms followed this for two months when pain was first felt across the sacral region, but later localized in the right sacro-iliac joint. In the beginning this pain was not continuous, but would come and go. It gradually increased in severity until disability resulted with continuous severe pain and marked deformity. The only comfortable position in bed was upon his back with right leg flexed at hip and knee. In a standing position his pelvis was flexed with the right side rotated forward and right leg flexed. He could not stand erect. Any attempt to do so caused great pain.

The x-ray picture showed eighteen diseased teeth. These were extracted with no improvement resulting. Medical treatment gave no relief. Patient had two or three chiropractic treatments which seemed to aggravate the condition. The patient was then under osteopathic treatments for two and one-half months, during which time thirty-eight treatments were given without relief. The patient came under our observation November 15 when he entered Hanover Hospital in Milwaukee. Under anesthe-

sia the affected parts were manipulated. This treatment was followed by complete disappearance of the deformity and pain. This boy returned to work in ten days and continued to work for six months when he had a recurrence of the deformity.

Stanley K.—aged 47. Had been disabled for two months with severe pain over the left sacro-iliac joint. He had been unable to stand erect since illness began. No previous history of illness or injury. His deformity was characteristic of these cases. He was taken to Alexian Brothers Hospital October 4, 1921. His back was stretched and manipulated under ether anesthesia. He left the hospital in six hours. He could stand erect without pain, the first time he was able to stand erect in two months. On October 11 he could stand erect without pain and could lie in bed on his face or back without causing discomfort. He returned to work November 14 and has had no recurrence of his trouble.

Louis R.—In March, 1920, reported that he had been having pain in the lower part of his back for several weeks. X-ray picture showed a deficient lamina of the fifth lumbar vertebra. The man claimed injury. He was treated by physicians. At one time he was in plaster for five weeks. On May 29, 1921, he could stand erect and had no noticeable deformity. On that day he was put to sleep, stretched and the back manipulated. On November 2, 1921, he said that for a time following the stretching, the back was improved. He, however, could not see that there was any permanent improvement. (This case is in litigation.)

John E.—Was examined October 11, 1921. He gave no history of illness or injury. He had been unable to work since April 14, 1921. Six weeks prior to October 11, characteristic deformity became extreme. He was unable to lie, sit, or stand with any degree of comfort. On October 11, he was put to sleep and stretched. He left the hospital the following day. On October 18 he could stand erect with both legs straight and heels resting on the floor, all this without pain. He returned to work November 14, and has had no recurrence.

Wm. H.—This man was seen October 18, 1921. He had not worked for three weeks because of pain about the right sacro-iliac joint. His pain was extreme when he was first examined. The pain was localized about the right sacro-iliac joint. There was no history of illness or injury. He was taken to St. Luke's Hospital on October 19, 1921. His back was stretched and manipulated. On the following day he complained of soreness over the back. Three days after the stretching he stood erect, bent forward and backward and could put a well marked curve in the dorso-lumbar vertebrae. He left the hospital October 29, and returned to work November 7. He has had no trouble since returning to work. Although free from pain at the time of my last examination, the right hip was shifted a little outward.

Thomas S.—Was seen October 20, 1921. This patient had been disabled

since January 1, 1921, with pain in the left hip over the sacro-iliac joint. The pain extended down the back of the thigh in the course of the sciatic nerve. His position in standing was characteristic of this trouble. On October 20th, under ether anesthesia we stretched and manipulated his back. He left the hospital two days later. He was able to stand erect without pain. Went home on November 29, at which time he was free from pain. He complained of some pain in the knee. He was able to work November 29.

Anton Z.—Was seen November 8, 1921. He gave a history of having been at work on top of a machine when it overbalanced and he was given a jolt which started pain in the left sacro-iliac joint. A skiagraph showed no pathology. The man was unable to stand erect. His left hip was thrown outward and backward. On November 8, under gas and ether he was stretched and back manipulated. He left the hospital on November 10. On November 14 he could stand erect, and walk, but complained of pain in the outer side of the leg. He went to work on November 25, but continued at work only two days. He then claimed that the work was too hard. He is not working at this time (March 1, 1922). He has no deformity and I am of the opinion that he is able to work.

The deformity and pain in the back have been corrected in ten out of the eleven patients worked on. In six of my eleven cases, the patient after a disability of from a few weeks to four months has returned to work within a week after the stretching and has continued at work without interruption. In three cases the pain and deformity in the back was corrected by the stretching, but some discomfort over the outer part of the calf and sole of the foot persisted. In one case the pain and deformity were relieved by the stretching. This patient returned and continued at work for six months when the deformity recurred.

In one chronic case where there was no perceptible deformity, the stretching proved of little value. This was in reality, a test case. I was desirous of knowing if the stretching process would prove of value in cases where there was no deformity.

### Conclusion

(1) Because of loose ligaments about the sacro-iliac joints there is a slight shifting of the bony surfaces which allows sufficient displacement to cause pressure on a nerve or on the periosteum.

(2) Cases with marked deformity respond best to this treatment.

(3) It is the writer's opinion that the body of the vertebrae might be crushed with too vigorous overextension of the thigh on the body.

(4) I am of the opinion that it is complete relaxation with direct pull that brings about the adjustment rather than the over extension of the thighs on the body.

(5) It is important that these patients cultivate a correct sitting and standing posture.

(6) Chronic cases of arthritis with little or no deformity do not lend themselves to this treatment.

The importance of this treatment is manifest to all physicians, especially those in the industrial field. Industrial surgeons have this condition presented to them almost daily and the

question for them to solve is, "Are pains in the back, frequently called lumbago, sciatica or arthritis, traumatic in origin?" My experience is that in a great majority of cases such pains are not traumatic in origin.

The contents of this paper may not be of material assistance in helping us to decide between traumatic and spontaneous back conditions, but it is of value to know that the distressing, acute arthritis of the sacral region, which heretofore has gone on for months, without change, may be relieved by a simple operation.

## The Physician in Industry

AT A RECENT meeting of the Conference Board of Physicians in Industry<sup>1</sup>, the following definition of the Physician in Industry was adopted.

The physician in industry is one who applies the principles of modern medicine and surgery to the industrial worker, sick or well, supplementing the remedial agencies of medicine by the sound application of hygiene, sanitation, and accident prevention; and who, in addition, has an adequate and cooperative appreciation of the social, economic and administrative problems and responsibilities of industry in its relation to society.

The discussion leading up to the formulation of this definition extended over several months. The questions were viewed from all angles and many suggestions were considered for including in the definition an outline of what his duties and functions were.

It was felt, however, that in order to avoid a complicated statement it would be better to include in a definition only the broad fundamental principles upon which the work of the physician in industry is based, leaving to subsequent elaboration the finer details. It was pointed out that the definition adopted should emphasize both the medical attainments and the industrial requirements of the physician engaged in this work in order to make his duties clear both to the medical profession and to industrial management.

It is assumed that the physician engaged in industrial work is well grounded in the fundamentals of medicine and surgery. He is, first of all, a physician. It is obvious, however, that this alone, while equipping him for satisfactory service in private practice, does not meet fully the requirements of industrial work. In his industrial experience he has, of necessity, to deal with questions of

sanitation, hygiene, and accident prevention as applied to large numbers of people working in comparatively close association. Only by special knowledge of the work in hand will the physician be able satisfactorily to discharge his duties. His knowledge of plant processes together with the physical examination of applicants for employment and of workers already engaged will enable him by judicious placement to reduce materially the accident and morbidity hazard and rate.

It must be realized that many of the qualifications for successful medical work in industry are of a non-medical nature, and call for a knowledge of the laws of social and industrial economics and of the administrative problems which arise in the conduct of an industrial medical department. The physician in industry must have a clear conception of the responsibilities of the industry to its workers and through them collectively to the community. On the other hand he should recognize clearly the duties of workers to the industry in which they are engaged. It is an intelligent appreciation and consideration of these problems that make for the success of the work of the physician in industry.

It is hoped that this definition will tend to remove misconceptions as to the work of the physician in industry, and establish his position and his work upon a basis satisfactory alike to the physician and to the industrial organization.

1. Membership of the Conference Board of Physicians in Industry is as follows:  
 Dr. John J. Moorhead, Chairman.  
 Dr. W. Irving Clark, Vice Chairman.  
 Magnus W. Alexander, Treasurer.  
 Dr. F. L. Rector, Secretary, 10 East 39th St., New York.

MEMBERS  
 Dr. E. B. Allen, Cheney Bros., South Manchester, Conn.

- Dr. T. John Bowes, Philadelphia Electric Co., Philadelphia, Pa.
- Dr. W. Irving Clark, Norton Company, Worcester, Mass.
- Dr. Royal S. Copeland, Health Commissioner, New York.
- Dr. R. P. Cummins, Midvale Steel Co., Philadelphia, Pa.
- Dr. Wm. J. Curry, American Thread Co., Holyoke, Mass.
- Dr. W. B. Fisk, International Harvester Co., Chicago, Ill.
- Dr. C. E. Ford, General Chemical Co., New York.
- Dr. Otto P. Geier, Cincinnati Milling Machine Co., Cincinnati, Ohio.
- Dr. E. H. Hanna, Cadillac Motor Car Co., Detroit, Mich.
- Dr. T. L. Hazlett, Westinghouse Electric & Mfg. Co., East Pittsburgh, Pa.
- Dr. E. H. Ingram, Wm. Crump & Sons Co., Philadelphia, Pa.
- Dr. J. A. Jackson, New York Edison Co., New York.
- Dr. A. C. Marshall, Powers-Weightman-Rosengarten Co., Philadelphia, Pa.
- Dr. S. M. McCurdy, Youngstown Sheet and Tube Co., Youngstown, Ohio.
- Dr. J. D. McGowan, Commonwealth Edison Co., Chicago, Ill.
- Dr. John J. Moorhead, Professor of Surgery, Post Graduate Med. School and Hospital, New York.
- Dr. Voyle A. Paul, The Yale & Towne Mfg. Co., Stamford, Conn.
- Dr. R. S. Quinby, Hood Rubber Co., Watertown, Mass.
- Dr. W. E. Ramsay, Raritan Copper Works, Perth Amboy, N. J.
- Dr. Wm. Alfred Sawyer, Eastman Kodak Co., Rochester, N. Y.
- Dr. F. E. Schuhmehl, General Electric Co., West Lynn, Mass.
- Dr. Loyal A. Shoudy, Bethlehem Steel Co., Bethlehem, Pa.
- Dr. A. K. Smith, E. I. duPont de Nemours & Co., Wilmington, Del.

### United States Leprosarium

Underwood & Underwood.

The largest lepers' home in America, at Carville, La., recently purchased from the State of Louisiana by the United States Public Health Service. This will be enlarged to care for the 3,000 lepers in the country. Dr. O. E. Denny will be in charge of the hospital. Congress provided for a national home for lepers in February, 1917, which was to be administered by the Public Health Service but the various states objected so strongly to such a hospital being established within their borders that it was not until four years later that the State Leper Home of Louisiana was acquired.

# ASSOCIATION LETTER

By WILLIAM ALFRED SAWYER, SECRETARY

**T**HE Seventh Annual Meeting of American Association of Industrial Physicians and Surgeons will be held in St. Louis, May 22 and 23, 1922, at the Medical School of Washington University. Members will reach their hotels by taking north bound Eighteenth Street car line at east side of the Union Station. Transfers are issued to all lines. For Jefferson Hotel, Missouri Athletic Association, Marquette Hotel and Hotel Statler transfer to east bound Page Avenue car. For La Salle, Laclede, Maryland and other downtown hotels transfer to east bound Olive Street car. To reach Washington University or Barnes Hospital from downtown, take Olive Street or Page Avenue car west and transfer to Taylor Avenue line at Taylor Avenue for the Medical School and Hospital.

The Department of Occupational Therapy and Orthopedic Shop of Barnes Hospital is in daily operation and will be available for inspection at a convenient hour—to be announced.

The Board of Directors will meet at the Statler Hotel, at eight o'clock, Sunday evening, May 21.

## TENTATIVE PROGRAM

WASHINGTON UNIVERSITY MEDICAL SCHOOL  
MONDAY, MAY 22—9:30 A. M.

Business Meeting

Remarks by the President.

Reports of Committees as follows:

(1) Committee to consider union with some section of the A. M. A. Dr. Otto P. Geier, chairman, Dr. C. E. Ford and Dr. William A. Snyder.

(2) Committee to report upon the relationship existing between the industrial physician and extra-industrial health agencies. Dr. Wade Wright, chairman, Dr. W. Irving Clark and Dr. Robert S. Quinby.

(3) Committee for the coordination and standardization of first-aid methods to be applied in industry. Dr. Loyal A. Shoudy, chairman, Dr. A. W. Colcord and Dr. Frank L. Rector.

(4) Committee on the standardization of records and a cost accounting system for medical service in industry. Dr. C. E. Ford and Dr. Frank L. Rector.

(5) Committee to evolve a practical scheme for supplying health service to small plants. Dr. C. F. N. Schram, chairman, Dr. C. D. Selby and Dr. Alfred E. Shipley.

(6) Report as to number of industrial hygiene departments in Federal, State and Municipal Health Departments. Dr. William A. Sawyer.

(7) Report of Committee to consider cooperation between the Association and the Conference Board of Physicians in Industry. Dr. Watson, chairman, and Dr. Otto P. Geier.

(8) Report of Secretary-Treasurer.

HOTEL STATLER—LUNCHEON

MONDAY—12:30 P. M.

Comments, by J. S. Newell, chairman, Superintendent, National Lead Company, Granite City, Ill.

The Physician in Industry Defined, by C. E. Ford, M.D., New York City.

Scientific Medicine and Surgery, by George W. Crile, M.D., professor of surgery, Western Reserve Medical School, Cleveland, O.

The Value of the Public Health, by Allen J. McLaughlin, M.D., president, American Pub-

lic Health Association, Washington, D. C.  
Human Conservation in Industry by Medical Supervision, by L. G. Harney, M.D., East St. Louis, Ill.

WASHINGTON UNIVERSITY MEDICAL SCHOOL  
MONDAY—2:30 P. M.

The Workingman's Diet, by John R. Murlin, M.D., professor physiology and director, Department of Vital Economics, University of Rochester, Rochester, N. Y.

Sickness Records in Prevention Work, by Edgar Sydenstricker, U. S. P. H. Service, Washington, D. C.

Mercantile Hygiene, by Arthur B. Emmons, 2nd, M.D., director, Harvard Mercantile Health Work, Boston, Mass.

Discussion by Dr. Harold W. Stevens, Jordan Marsh Company, Boston, Mass.  
Occupational Diseases and the Physician in Industry, by A. G. Cranch, M.D., National Carbon Company, Cleveland, O.

Studies of Undernourishment in Industry, by Wm. Hall Bunn, M.D., Youngstown, O.

Discussion by R. W. Elliot, M.D., National Lamp Works, Cleveland, O.

Importance of Periodic Physical Examinations—with Reports on Three Thousand Examinations, by W. B. Fisk, M.D., chief surgeon, International Harvester Company, Chicago, Ill.

Discussion by R. S. Quinby, M.D., Hood Rubber Company, Watertown, Mass.

WASHINGTON UNIVERSITY MEDICAL SCHOOL  
TUESDAY—9:30 A. M.

The Practical Application of the Activities of the Public Health Service to the Problems Affecting Industry and Industrial Physicians, by L. E. Thompson, M.D., Surgeon in charge, Division Industrial Hygiene, U. S. P. H. Service, Washington, D. C.

Surgical Reconstruction (Illustrated), by R. Tunstall Taylor, M.D., professor of orthopedics, Johns Hopkins Medical School, Baltimore, Md.

The Heart in Industry, by Paul D. White, M.D., chief of the medical out-patient departments and in charge of the cardiac clinic, Massachusetts General Hospital, Boston, Mass.

Discussion by Arthur E. Strauss, M.D., St. Louis, Mo.

The Relation of Inguinal Hernia to the Workmen's Compensation, by J. M. Wainwright, M.D., chief surgeon, Glen Aiden Coal Company, Scranton, Pa.

Discussion by Dr. Loyal A. Shoudy, Bethlehem Steel Co., Bethlehem, Pa.

Unusual Fractures and Dislocations with End Results (Illustrated), by C. W. Hopkins, M.D., chief surgeon, Chicago & Northwestern Railway, Chicago, Ill.

Discussion by Dr. George D. Cale, St. Luke's Hospital, St. Louis, Mo.

Atmosphere, Efficiency and Civilization, by Ellsworth Huntington, Department Geological Sciences, Yale University, New Haven, Conn.

What Should the Industrial Physician Know About Nervous and Mental Diseases, by Frankwood E. Williams, M.D., National Committee for Mental Hygiene, New York City.

Cafeteria lunch—served in the restaurant of the Medical School.

WASHINGTON UNIVERSITY MEDICAL SCHOOL  
TUESDAY—2:30 P. M.

Election of officers.

The Relation of Syphilis and Gonorrhea to Industry, by Wm. F. Snow, M.D., general director, American Social Hygiene Association, New York City.

Discussion by Dr. A. N. Thompson, New York.

Industrial Groupings and Tuberculosis, by William Charles White, M.D., director, Tuberculosis League, Pittsburgh, Pa.

The Industrial Phase of the Tuberculosis Problem, by Frank A. Craig, M.D., physician in charge of industrial work, Henry Phipps Institute, Philadelphia, Pa.

Industrial Results of Granite Dust Inhalation, by C. Jarvis, M.D., Barre, Vt.

When this issue reaches you, you will, of course, be ready to start your trip to St. Louis to attend the annual meeting, a program of which is con-

tained in this issue. The program is a promising one and much value should result from it.

Registration for the meeting will take place at the Medical School, Washington University. Such hotel headquarters as we will need, will be at the Hotel Statler, although the only meeting to be held there is the luncheon meeting on Monday.

The membership campaign continues to go forward and we hope that by the time of the annual meeting, a substantial increase in membership can be reported.

The following are some of the new members: Drs., James C. Graves, Jr., Travelers Insurance Company, Hartford, Conn.; F. G. Barr, National Cash Register Company, Dayton, O.; R. W. Angevine, Eastman Kodak Company, Rochester, N. Y.; S. R. Light, The Upjohn Company, Kalamazoo, Mich.; S. R. Downing, Standard Oil Co., Richmond, Cal.; J. F. Lewis, M. P. Zinc Company, DePue, Ill.; P. J. Bowman, Union Lumber Company, Ft. Bragg, Cal.; L. St. J. Hely, The Pullman Company, Richmond, Cal.; O. S. Klug, Armour & Company, E. St. Louis, Ill.; W. F. McNary, (various industries) E. St. Louis, Ill.; Klye B. Steel, New York Federal Reserve Bank, New York City; E. M. McCarty, Oxford Paper Company, Rumford, Me.; R. W. Burnett, Pine View General Hospital, D'Lo, Miss.; Richard Kemel, Tropical Oil Company, Cartagena, Colombia, S. A.; David F. Armstrong, International Harvester Company, Auburn, N. Y.; G. F. Greenleaf (various industries) Alton, Ill.; J. M. Barnett, (lumber camps) Albany, Ga.; and A. N. Dykes, (various industries) Columbus, Ga.

If for any reason you are not receiving the official journal of the Association, together with the abstracts and other literature, please notify the secretary. It is always possible for mistakes to creep in and the secretary believes the members will bear with him when such things happen.

As you doubtless know, the Secretary has other things to do besides attending to the affairs of the Association. He will appreciate it if members will take the initiative of sending information that will be of general interest.

Matters of great importance will be taken up at the business meeting and it is hoped that as many as possible will try to be there Monday morning so that the business may be transacted expeditiously.

## Recent Compensation Decisions

THE Supreme Court of Pennsylvania, January 3, 1922, held in a proceeding under the Workmen's Compensation Act to obtain compensation for the death of an employee struck by the crank of a crab that the medical testimony showed that the accident was a contributing cause in the development of tuberculosis which resulted in his death. The theory is that the shock rendered him subject to the quick development of the disease and that such development was due to the injury.

The facts in short are that Kelley was a carpenter in the defendant's service and was injured March 19, 1918. He had been employed by the coal company for three years prior to the accident, was a "steady worker" and lost no time on account of illness, although not a robust man. He was winding a crab, "turning over a car to make some repairs on its bottom, when the crank flew out of his hands striking him on the head and at a point on the left side of his abdomen near the waistline knocking him down. The head was quite badly cut, but the injury to the body was not at first considered serious. . . . Five days after the injury he complained of injury in the region of the left testicle, which, upon examination, was seen to be swollen, inflamed, and tender; subsequently, about a month after the accident, an operation was performed to remove the testicle, and it was found to be infected with tubercle bacilli; following this, deceased had trouble with his hip and a general consumptive condition developed. On November 6, 1918, he died at the age of forty-six of "tuberculous peritonitis."

"There is ample medical testimony on the record to sustain the findings. . . . Under our cases, this was sufficient to warrant and sustain the award."—*Kelley v. Watson Coal Co.*, 115 A. 885.

THE Supreme Judicial Court of Massachusetts, January 7, 1921, held that the evidence in the following case was sufficient to warrant the finding of the Industrial Accident Board that the employee's death was caused by lead poisoning suffered in his employment.

The employee had worked as a plumber since he was twelve years of age; he was thirty-nine at his death. The family physician testified that he had treated O'Donnell for the last

few years "for what he supposed was lead poisoning. There was evidence that during the five months of his employment with Cronin, the assured, he was handling lead pipe, and his handkerchiefs and napkins would be colored red from red lead. On the testimony of the specialist it could be found that the lead poisoning which was a contributing cause of the employee's death was progressive, and probably due to the constant assimilation of the lead during the years he had been exposed to it. Without further reference to the evidence in detail, it is apparent that we cannot say that the finding of the Board was unwarranted."—*O'Donnell's Case*, 133 N. E. 621.

THE Supreme Court of Errors of Connecticut, November 3, 1921, held that where a painter who was working on a staging was subject to attacks of indigestion which in turn caused temporary unconsciousness, his death which resulted from a fall from the staging caused by temporary unconsciousness was due to an attack of his ailment and constituted an "injury arising out of his employment."

The facts of the case follow: "The deceased had worked as a painter for the defendant for two years and had painted structures at a height above the ground without being affected by it. He began September, 1918, visiting physicians for their prescription. None of the physicians told him his trouble, indeed they did not agree as to this. From time to time prior to April 15, 1920, he had spells of unconsciousness, but he had always been able to anticipate these and take firm hold of some support, and after temporary loss of consciousness he would resume work." The defendant knew of these spells of unconsciousness. About three months before the date of his injury a physician advised him to quit working in high places but he felt the necessity of work and had to continue this occupation. On the morning of April 15, 1920, he was given the choice of doing outside or inside work. He was not feeling well and selected outside work. He became sick at his stomach, went to the defendant's dispensary where he was given medicine to relieve him and returned to work. On returning from the dispensary he worked awhile, and then, apparently again feeling uncomfortable, he sat down on the plat-

form where he was painting, smoked a cigarette, stood up, or partly stood up to resume work, and then fell backward to the surface below and fractured his skull as a result of the fall from which he died."

Two points are raised in the opinion of the court: First, did the death of Gonier, resulting from a fall from staging, caused by a temporary unconsciousness due to disease, constitute an injury arising out of his employment. . . . Second, did Gonier's conduct in working upon this staging constitute willful and serious misconduct?"

The opinion of the court will not be quoted. As to the first point it was said: "Gonier's employment brought him upon this scaffolding from which if he fell he was in danger of serious injury. The danger of falling and the liability of resulting injury was a risk arising out of the conditions of his employment."

Secondly, it was not willful and serious misconduct for him to resume his work. If his conduct could be held to have been misconduct, it would be difficult to hold it to have been serious misconduct. But, aside from this, it could not be held to have been willful. He did not continue to work at this time of his liability to suffer one of these spells of unconsciousness which would be likely to cause him to fall, so that his course could not be found to have been done purposely with knowledge. Neither could it be said that the circumstances show on his part a reckless disregard of consequences for his own safety.

The Superior Court is advised to affirm the award of the Compensation Commissioner."—*Gonier v. Chase*, 115 A. 677.

THE Appellate Court of Indiana January 5, 1922 held that disability from disease which is contracted by drinking polluted water is compensable as an "injury by accident." The appeal was made from an award by the Industrial Board in favor of appellee. No question was made "as to the sufficiency of facts to sustain the award, but the sufficiency of the evidence to sustain the finding of facts is challenged."

The appellee was in the employment of a cabinet factory which furnished its employees while at work drinking water from a well in its factory through pipes. This water was pumped by means of a steam engine and flowed constantly during working hours. Without appellant's knowledge, the water from this well, so furnished its said employees became contaminated by seepage from a toilet in its said factory. "Appellate while working used the water for drinking purposes without knowledge

of the pollution, became infected with typhoid, and was in bed several weeks. The Industrial Board found that the appellee "received a personal injury by accident arising out of and in the course of his employment." Appellant contends that the evidence does not sustain finding but "merely shows that appellee suffered a disability from a disease for which compensation is not authorized."

The court held that the entrance

of typhoid germs into appellee's intestines "by reason of drinking the polluted water furnished him by appellant for that purpose, while in its employ may rightfully be termed an 'accident.' Disregarding the fact that typhoid is not inflammation occurred with resulting fever which constituted an injury within the meaning of the Workmen's Compensation Act."—*Wasmuth Endicott Co. v. Karst*, 133 N.E. 609.

## Neuropsychiatric Examinations

IN ORDER to determine the causes for "nervous instability" among Harvard students, a brief neuropsychiatric examination was added in 1920 to the routine physical and orthopedic examinations. Dr. Stanley Cobb, M.D., Assistant Professor of Neuropathology, Harvard Medical School, and Assistant Neurologist, Massachusetts General Hospital, at the instance of Dr. Roger I. Lee, Professor of Hygiene, planned and supervised the examination, report of which is contained in the February issue of the *Journal of Industrial Hygiene*.

Four main questions were investigated in order to avoid diffuseness. These were: (1) What is the incidence of neurotic history in the group; (2) can any physical sign be taken as an indication of nervous instability or as indicating that the individual is potentially unstable; (3) is endocrinopathy common, and what is its relationship to nervous instability; (4) after four years of observation, do the men who showed certain symptoms at their first examination tend to fall into significant performance groups?

The examination consisted of questioning concerning history of syphilis, habits and sleep, examination of pupils, thyroid, heart rate and rhythm, blood pressure variation with posture and knee jerks. Other questions were added to bring out history of any previous neurosis and a group of physical observations which would bear directly on abnormalities of the nervous system, especially the vegetative nervous system which is known to be affected in neurotic and psychotic conditions.

The examination was carried out by a group of eight physicians familiar with the routine examination.

The examination revealed a neurotic history in 188, or 16.4 per cent of the 1,141 men examined, as shown

by a history of one or more of the following troubles: Abnormal mood or difficult adaptation; nervous symptoms in past; convulsions; chorea; bed-wetting; night terrors; sleep-walking; stammering; severe nervous breakdown; nervous symptoms at present.

The men with neurotic histories differed physically from those with no such history only in more frequently showing exaggerated knee jerks, rapid heart beat, and other vasomotor phenomena such as dermatographia, flushing, excessive sweating, and palpitation, but these symptoms were found in the men with neurotic histories only 6 to 10 per cent more frequently than in others.

The presence of tremor, dilated pupils, acne or variations in blood pressure with change of position did not seem to be significant in this connection,—i.e., these symptoms occurred just as frequently in the men with no history of nervous instability as in those with such a history. Only by following up the individuals with neurotic histories for years can it be determined whether they are more liable to future breakdown than are the other men.

The summary of the results showed that family history, past history, and present complaints form the best guide to nervous instability; that vasometer instability was found somewhat more frequently in the men with neurotic histories; that tachycardia, blood pressure variation, and dermatographia were often found associated with each other and with exaggerated knee jerks. Men with albuminuria were likely to show all these symptoms.

Examinations also showed that endocrinopathy was rare, but the small number of cases discovered showed more symptoms referable to the vegetative nervous system and less neurotic history and acne. In

men with bad mechanical use of the body, tachycardia, arrhythmia, high blood pressure, and variable systolic pressure were more common than in those with good mechanical use. It was also found that men with good bodily mechanics passed better psychological examinations than did those with poor bodily mechanics and poor posture.

## Colored Women as Industrial Workers

The Consumers League of Eastern Pennsylvania has just published a study of the position of colored women in industry today. Some twenty-eight industries and seventy-four processes were found in which colored women were working. The type of work was as a general rule unskilled.

In short, it may be said "that the colored women's position in industry compares with the white women's position as the white women's compares with the man's."

Irregularity in work, slovenliness in work habits, and the other criticisms of colored workers might be applied to any group of untrained, unorganized workers who are bound to float from job to job in an effort to make ends meet. The inadequacy of the colored women's wages may be a fundamental difficulty. Eighty per cent of the women were earning less than the minimum wage of \$16.50 which was recently established by the Minimum Wage Commission of the District of Columbia. This \$16.50 is raised to \$16.76 by the Consumers League as the minimum which would support a working girl at the time the study was made. Fifty per cent of the colored women earned actually less than ten dollars a week. The vicious circle of low wages among un dependable workers is recognized. Irregularity in employment is the inevitable result of such wages. The report cites one girl as typical of this group. Earning only seven dollars to nine dollars a week and paying \$6.50 of this for room and board, she was continually running short in her budget. At such times she would return to domestic work and save, eventually seeking factory work again. Then there was the girl who worked in a candy factory for eight dollars a week and left for a boarding house position at eight dollars a week and meals with Saturday afternoons and Sundays off.

The report makes recommendations to workers, to employers, and to the public pleading for social and industrial policies which will permit a fair chance for colored industrial workers.

# INSTITUTIONAL HEALTH

*The Health Problems of Schools and Colleges, Hotels, Summer Camps, Children's Homes and Homes for Dependents*

## Dangers in the Hospitalization of Normal Babies

There Is No Adequate Substitute  
for the Home Nurture of the Child

BY A. LEVINSON, CHICAGO, ILL.

A NORMAL baby is an anomaly in a hospital except during the first few days of its life. Unfortunately, however, nearly every children's hospital harbors a few normal babies most of the time. These babies are usually sent to the hospital not by physicians but by social workers, and it is up to those concerned to familiarize themselves with the indications and counter indications for sending such cases into a hospital, and it is the duty of the physician to know the behavior of such babies in hospitals and the precautions to be taken while there.

Experience has shown that normal babies are sent to a hospital for one of three reasons: (1) sickness of mother; (2) illegitimacy; (3) examination for adoption. Although all three of these causes constitute good reasons for removing the baby from home, a great deal of judgment must be exercised before decision is made to place the baby in a hospital. It is to be remembered that hospitals are not made for normal babies; that hospitals are built and maintained for sick infants and children, and that a hospital is neither a home for orphans or the friendless nor a boarding school nor a place of exhibition. Unless these points are kept in the foreground the hospital is likely to be put to many uses other than the treatment of the sick.

The strongest argument against placing a normal baby in a hospital is the fact that very few normal babies thrive while in a hospital. However much care the baby gets, he does not as a rule gain in weight. He

*Stereotyped method, standardized routine, and sanitary platitudes call forth scant response from the growing child, who is almost uniformly found to be retarded under institutional conditions.*

*The hospitalization of the normal child is therefore to be avoided and provision for its cure must as nearly as possible approach the ideal condition of one home, one mother for each child, with full opportunity for the development of its mother's capacities.*

often even loses in weight. In addition to remaining stationary in weight the baby lacks the required exercise through the play that should be furnished to every normal baby. Above all, it is a well known fact that babies in institutions contract infectious diseases much more quickly than they do at home. The reasons for this are apparent. First of all, the baby comes in contact with other children. Even if the hospital is equipped with a special room for normal babies there is always this chance that some baby may bring in an infectious disease and give it to all the other inmates. Secondly, the lack of exercise and fresh air lowers the vitality of the baby and exposes him to infection. More than one baby has entered a hospital in a normal state of health and contracted diseases while there. It is, therefore, the duty of everyone who is con-

fronted with the problem of removing a baby from home to exercise a great deal of judgment and to limit to the very minimum the number of babies to be placed in hospitals.

Sickness of the mother possibly constitutes the greatest reason for placing a baby in a hospital. Relatives and neighbors will often take care of the baby of a sick mother for a few hours or a few days but seldom will they care for it for any longer time. Under the circumstances, it would be most advisable to place the baby in a private home. However, when that is impossible, the baby must go to a hospital.

Illegitimacy should by right constitute no reason for placing a baby in a hospital. As a rule, however, the baby is not placed there by any physician or social worker. It remains there after birth when the mother leaves the maternity hospital and she has no means of supporting herself, still less of supporting the additional burden, the baby. It is, therefore, often a problem that cannot be solved by the hospital authorities and under present conditions cannot be prevented.

Examination for adoption should by right keep a baby at a hospital only a day or two to allow the physicians to make a physical examination and do a Wassermann test. At times, however, after the baby has entered the hospital the people who were to adopt it change their mind and the social agency has to keep it there until some other family decides on its adoption.

Whatever cause brings a baby

to a hospital, once there it should be the aim of the hospital staff to keep it in its normal state of health and to send it out as soon as possible. Neither of these objectives is very easily accomplished, but unless the problem is constantly considered, the life of the child might be endangered.

One of the first precautions to be taken is not to have the normal baby come in contact with sick babies. The ideal state of affairs would be to put each baby in a separate room. This, however, would involve a tremendous expense on the part of the hospital. The next best thing possible is to have a special ward for normal babies. Of course, the great question comes in as to how one is to know if the baby is normal when it enters the hospital. If possible, every baby should be isolated for two or three days before it enters the general normal ward.

The ward should be spacious and well ventilated. Normal babies require a great deal of air especially while at the hospital. The air does not need to be cold. The room should have fresh warm air.

The ideal way is to have a nurse for each baby. Nature has seen the wisdom of it and supplied each baby with a mother. It is only very seldom that Nature makes the mistake of supplying one mother with more than one baby at the same time. It is unfortunate, however, that hospitals cannot supply all the wants of the baby in an ideal manner. The mere fact that a baby goes to a hospital speaks for its being unfortunate and no ideal conditions can be expected.

It is, however, essential that each baby gets its full quota of care and this can be done only when a nurse has sufficient time to give a child a fair amount of attention. No more than five normal babies should be cared for by one nurse. Experience has shown that nurses cannot take care of any greater number than that.

Each infant should be supervised during its feeding period so as to prevent accident. There is as yet no substitute for human supervision in feeding babies. There are many bottle holders on the market some of which work fairly well, but no bottle holder is as good as woman's hands.

Each child should be exercised at least once a day. There is a difference between holding a baby all day and picking it up for a few minutes

during the day. Babies who lie on their backs all of the time develop respiratory diseases very readily.

Picking a baby up for a few minutes does not spoil him. On the other hand it helps to exercise it and, while the baby learns to exercise its muscles by kicking with its feet, it does not exercise the muscles of its back with ease.

A nurse who takes care of normal babies must be in good health. Experience has shown that when the nurse has a cold she transmits it to the baby, just the same as when the

mother has a cold the baby usually gets it.

As soon as a normal baby gets sick at the hospital it should be removed from the normal nursery. An ordinary cold contracted by one baby will spread like wildfire to all the babies in the ward. With all these precautions, it might be impossible for the hospital to keep normal babies well for an extended length of time. It should, therefore, be the aim of everyone who is confronted with the problem of the normal baby in the hospital to remove it in as short a time as possible.

## Blind Read Newspapers

**B**RAILLE raised type must today bow to the Otophone's five musical notes. The blind man can now read to the purr, whine and rhythm of this new machine. Motifs recently worked out on the Otophone enable the sightless, with a little practice, to read the daily papers; something they have never before been able to do as no newspapers are translated into raised type.

reflected back and transformed into sounds by means of selenium cells and is heard by the use of a very sensitive telephone headpiece."

Rays of light which automatically travel across the printed page a line at a time from left to right are somewhat similar to the five musical notes—sol, do, re, mi and sol again. Each of the twenty-six letters in the alphabet has a different sound. Plain

Keystone View Company.

The new instrument was invented by Professor E. R. Fournier d'Albe, M.R.L.A., former lecturer on physics at the University of Birmingham, England, and one of them is now in operation at the Federated Engineers Development Corporation in Jersey City. Mr. Thomas H. Ormsbee in a recent article in the Editor and Publisher Magazine describing the Otophone says that it is "a beam of light, projected through a tiny lens, streaming through five rows of oblong perforations in a revolving disk, which is

white paper produces no sound at all.

The machine works with any common size of book type printed on white paper, and will also produce sound waves from typewritten copy.

Because of the delicacy of the mechanism it is impossible to place the machine on the market for less than \$600, and while at this price it is beyond the average purse it has been suggested that Otophones be installed at certain places where the blind could use them in reading daily newspapers, magazines and books.

# Preventive Measures Protect Nursing Group

By GEORGE F. DICK, M.D., CHICAGO, ILL.

THE following study was begun in January, 1920, with the idea of possibly cutting down the time lost from duty on account of sickness by the student nurses at the Presbyterian Hospital. The work was started not because the time lost was considered excessive, but because the situation seemed to offer an excellent opportunity for preventive procedures. There is a community of about two hundred nurses in which cooperation was secured with exceptional willingness and intelligence, and it appeared that such a study would be of general interest, especially to those concerned with preventive and industrial medicine.

A record was kept showing the diagnosis; the place where the nurse was on duty when the sickness was contracted; the number of days ill in the hospital; and the total time lost from duty. An analysis of the data collected in one and a half years shows that during the year 1920, there was a loss of 1,651 days, or about four and a half years: equivalent to the loss of more than four nurses throughout the year, in addition to the time involved in the care of the sick nurses. During this time the number of days spent in the hospital was 560.5. If the average cost of the room occupied is taken at five dollars a day, this results in an expense of \$2,800 a year. Table I shows the days of hospital care and the total time off duty in six months periods, and the totals for the year 1920 and for the 1½ year period over which this study extended. In order to learn which diseases are most important from the standpoint of hospitalization and time lost, Table II was constructed.

It is seen that of the thirty-eight diseases into which the sickness can be classified, only four caused totals of more than one hundred days off duty. Of these, tonsillitis is first with a total loss of 484 days in one and a half years. Scarlet fever is next in importance with a total loss of 340 days. Influenza follows with 337 days, and arthritis is last with 142 days. From a preventive standpoint, in this instance, influenza may be neglected as it was present in epidemic form. It occurred only during January and February, 1920, and does not constitute a regularly operating cause of time loss. The arth-

ritis cases were of the rheumatic type, and not only associated with tonsillitis in most instances, but relieved by the removal of tonsils.

At the end of the first six months study, it was apparent that tonsillitis, scarlet fever, and arthritis are the diseases toward which preventive measures should be directed. Since in each of these diseases, the throat is commonly the portal of entry, we hoped to lessen the incidence of all three by preventive measures directed against throat infections among the nurses. The following measures were employed: (1) Complete physical examination of the nurses at the beginning, instead of at the end, of their period of probation. (2) Early iso-

lation. Nurses were urged to report sickness as soon as possible, and every nurse with a sore throat was isolated as early as possible whether or not she had a rash. (3) Removal from hospital for a time following recovery. As soon as recovered, the nurses were sent home for a time before they were allowed to return to duty. (4) Tonsillectomy in those individuals having repeated attacks of tonsillitis; and especially in those who also had arthritis, tonsillectomy was done. As a rule this was not done within one month following an acute tonsillitis, and usually the operation was done before a vacation. In the one and a half years, no sore throats have been seen in individuals with complete

Burns	1	0	1½	0	0	0	0	0	0

tonsillectomy and adenoidectomy, and in those cases associated with arthritis there has been freedom from subsequent arthritis (Table III).

The results of these measures are too striking to be attributed entirely to coincidence. In Table III a comparison of the January to July periods of 1920 and 1921 shows that the total time lost from tonsillitis in the first six months of 1920 was 315½ days; while in the first six months of 1921, it was but 130 days. There was a reduction from 279 days to sixty-one days in the loss of time due to scarlet fever. The time loss caused by arthritis was reduced from 131 days to 11 days.

Certain circumstances attending the incidence of the diseases responsible for the greatest loss of time are deserving of attention. For example: an analysis of the records shows that of all the tonsillitis cases, 42 per cent occurred in nurses on duty in the children's ward, and 50 per cent of all the cases of scarlet fever occurred in nurses on duty in the same ward. The remaining 58 per cent of tonsillitis and 50 per cent of scarlet fever were equally distributed through out the hospital.

A Summary of Findings

The diseases which caused the greatest loss of time during one and

a half years, are in the order of their importance; tonsillitis, scarlet fever, influenza, and arthritis. Influenza was present only during two months when it was epidemic. Following preventive measures directed against throat infections among the nurses, there was a reduction of 58 per cent in the time loss due to tonsillitis; 78

per cent in the time loss due to scarlet fever; and 91 per cent in the time loss due to arthritis.

John P. Fletcher, Major Medical Corps, U. S. A. has an article describing a "Proposed New First Aid Packet" in a recent issue of *The Military Surgeon*.

Boy Scouts In First Aid Drills

Underwood & Underwood.

With hundreds of thousands of boys being trained in the principles of health and first aid, the future for health education in the United States looks promising. New York Boy Scouts gave an exhibition of their skill in bandaging and stretcher bearing during a recent field hospital day in Central Park.

# Relation of Social Work to Mental Hygiene\*

BY MARY C. JARRETT, ASSOCIATE DIRECTOR, SMITH COLLEGE TRAINING SCHOOL FOR SOCIAL WORK, NORTHAMPTON, MASS.

IN DEALING with the relation of social work to mental hygiene only mental hygiene for the individual will be discussed in this paper. In the other activities of the mental hygiene movement, such as public education, surveys, promoting legislation, creating hospitals and clinics, social work may also have a part, but we have now to consider what the social worker may do toward promoting mental health in the individual. And there are two groups of social workers who must be considered: (1) The special group of psychiatric social workers who are specially prepared for work with cases of mental trouble; and (2) all other social workers, whose cases come to them by reason of social, economic, or physical trouble, but very often present psychiatric problems.

All social workers necessarily deal with mental troubles, big and little; and they have an unusual opportunity to teach and apply the principles of mental hygiene in their practice. The old popular idea that mental hygiene had to do only with insanity and feeble-mindedness is dying out and we are beginning to realize that mental hygiene is as important for all of us as physical hygiene, and that it is doing its best service when it keeps people well and active. So in the last five years there has been a very general recognition among social workers that they need to know a good deal about mental hygiene.

The psychiatric social worker has elected to work in association with the psychiatrist upon cases of mental disorder or defect, and has received special preparation for this work. A wide range of patients need the psychiatrist's care, including not only those who are acutely ill and others who are on the way to becoming ill, but also those who have slight mental difficulties that might never amount to an illness but cause discomfort, just as a chronic cold or a weak ankle may be a nuisance. So it is among a widely varied group of persons that the psychiatric social worker is employed. Because she is known to be familiar with mental disease, she is often embarrassed by being asked to diagnose mental cases. One social

worker I know has at last with considerable difficulty and embarrassment persuaded her community that she is not "a psychiatrist." She has had to explain copiously that psychiatry is a branch of medicine, that diagnosis and treatment of mental disease require first, medical knowledge, since bodily and mental conditions are so closely related, and second, a very considerable knowledge of psychiatry, since mental disease is extremely complicated. In psychiatric problems the psychiatric social worker cannot properly function alone, but only as an assistant to the physician.

## Supplements Psychiatric Inquiry

A psychiatric social worker in Boston once received a long distance call from a lady in a Connecticut town asking her to come down and examine a young nephew who was giving his family much anxiety by unreasonable conduct. She explained that she was not a physician and advised taking the boy to a certain psychiatrist in New York. She has often wished since that she might have gone in response to the call, and made a social examination, for the assistance she could have given the psychiatrist who saw the boy might have been an important addition to the treatment. If she had gone down, her first duty would have been to get the history of the child from his family, the way he was born and grew, the influences and experiences that developed him, his tastes, his behavior; then from teachers and others who saw the boy frequently she would set out to learn what they had observed; a talk with the child would suggest whether his attitude called for special lines of inquiry; and, finally, she would need to observe the home and the boy's attitude toward his family. This history given to the doctor before he saw the patient would not only have saved him time, but would have given him more accurate and reliable and also fuller information than he could get from one or two relatives who might accompany the boy. It would also have shown the possibilities for carrying out the desired treatment in the boy's natural environment. Then, after the psychiatrist had made his examination, the social worker would have been able to work out with the

family means of carrying out the treatment advised. Furthermore, she might have found in that locality some one sufficiently informed to make accurate and unbiased reports of the boy's progress to the physician.

Almost every case of mental disorder has some social complication. Persons who are mentally ill are apt to create all sorts of social disorder. On the other hand, mental illness is often the result of inability to meet social demands, and in many cases the conditions necessary for proper treatment can be brought about only through social work.

Psychiatrists who have proved the value of social work say that without the assistance of social workers they are unable in a majority of cases to do justice to their patients. The importance of social work in connection with psychopathic hospitals, out-patient departments, and court clinics is now pretty thoroughly recognized. Unfortunately the potential psychiatric social worker is not so well aware of her importance as are those who need her help. There are not nearly enough persons in training for this work to fill the positions that need them. In a recent report by Dr. Thom and Dr. Singer on "The Care of Neuro-Psychiatric Disabilities," in the Veterans' Bureau, the statement is made that "To do the patient justice it is essential to supplement by outside investigation. For this purpose a well organized social service is necessary." And then this statement follows: "The greatest need at the present moment is for trained personnel. It is unfortunate that neuro-psychiatric medical officers, nurses, and social workers, exist only in limited numbers, in no way commensurate with the demands."

The social worker in other fields of medical and social work has a remarkable opportunity to teach mental hygiene to her clients. Whatever the reason that brings the client to a social agency—unemployment, sickness, desertion, illegitimacy, or misconduct—the practice of the social worker is essentially the same. The first step is to find out the real cause of the individual's inability to get on. The social examination consists of inquiries from persons associated with the client and from public records. It may be that the trouble

\*Read before a mental hygiene conference under the auspices of the Connecticut Society for Mental Hygiene, Bridgeport, Conn., December 2, 1921.

lies in one or all of the five classes of evil that Dr. Southard classified in his "Kingdom of Evils,"—disease, ignorance, bad habits, legal entanglements, poverty, or resourcelessness. The client may be sick, ignorant, victimized by bad habits, involved with the law, and lacking financial or other resources; or he may be suffering from only one or two of these evils. It is the duty of the social worker to help him to organize his affairs in a way that will bring about the best adaptation to his environment that is possible for him, and to correct or reduce the evils from which he is suffering. He may require the services of various professional groups. Doctor, teacher, clergyman, and lawyer may all be needed in one case; but, while each is dealing with the individual in some particular relationship, the social worker is concerned with all the relationships that make up his life. It is the social worker's duty to get these relationships working together to keep the individual adjusted to his environment as well as possible.

So whatever the client thinks is the matter with him, this is what the social worker should do for him—examine his case to find out what is at the root of the trouble and then endeavor to get him into as thoroughly sound social condition as possible. A good social worker should not be satisfied to give a client merely a vacation or a job because that was what he asked for, any more than a good doctor would give a patient a plaster or a brace because he asked for it.

It is well known that there is a good deal of prejudice in the community against the social worker and the sort of social practice I have indicated. This is natural enough, for things that we do not understand are usually distasteful to us, and the theory and principles of social work are still little known. We find traces even yet of distrust of medical examination. Some people like to go to a doctor and say, "Please give me a pill for my headache," and get the pill with no questions asked. There is still some medical practice of this sort for those who like it, and a good deal of social work of the same kind is still being done. But the kind of social worker who will help to promote mental hygiene is the one who is trained to study the clients' cases thoroughly and to endeavor to bring him into good social condition.

Another objection advanced is that to help a person arrange his affairs and

to smooth the environment for him is to undermine his moral character. Since we grow by struggle, it is said our development is likely to be impaired if the struggle is made easy. This it seems to me is like saying let a man be bound with ropes, so that he may by struggling develop his muscles. The people who need the care of a social worker are so bound by a network of circumstances that they are not able to use their powers of self-development. What chance for growth has a sick woman with four children and the fear of another, a quarrelsome husband not providing enough to feed and clothe the family, and a house only partly furnished? A good deal of social treatment is needed before such a patient is able to use her own powers freely.

### Need of Social Work General

Social work does not remove the necessity for individual initiative but it aims to remove obstacles that throttle initiative and to stimulate the use of initiative. And the need of social work is not confined to any class of persons. In hospitals and clinics, it has been shown that it is not the poorer patients only who need the social worker. It is clear that social disorder occurs among all classes. The well trained professional social worker could with equal benefit study and advise patients among all classes. In the course of time it may become the custom to seek the advice of the social worker as freely as we consult the doctor or the lawyer.

It is hardly necessary to dwell on the importance of knowledge of mental hygiene for all social workers. The adjustment of human relationship calls for knowledge of personality and how it is developed. Moreover, since fully half the clients of social agencies present some psychiatric problem, it is obvious that every social worker should know some psychiatry. Lack of such knowledge is now causing a good deal of waste in many social agencies. Here is such an instance. A man was referred to a relief agency during a period of unemployment. He and his home made a good impression. Employers said he lost jobs because he did not get on with fellow employees. As his former work did not give scope for the mechanical ability he had, efforts were made to get him work in a mechanical line on the supposition that he would be less contentious if more interested. For a year various different jobs were found. Then he had to be sent to a tuberculosis sanitarium,

where he was discharged because he was "nervous and restless." A mental examination was now secured. The man was understood by the social worker to be abnormal but not committable and efforts to get him jobs were resumed. His plight grew worse and worse and finally he went himself to a mental hospital and was committed. While the agency did secure a mental examination for this man a year and a half after he first came, he was not treated as a sick person even then.

The view that social case work is the endeavor to bring a person into right relations with his environment after a study of all his relationship and that it is applicable to all classes must prevail to a much greater extent that it does at present before social work can be used to the greatest advantage in the two fields where the best opportunities for preventive work lie—industry and the schools. These are the two places where large numbers of persons are gathered together regularly for a large part of the day. Here is the opportunity to detect the first signs of social difficulty. The earliest indication that the individual is not going to get on may be a physical symptom, a mental symptom, or a social symptom. The social worker should be trained to see all these signs before they cause acute trouble.

In the schools, the movement for visiting teachers is making steady progress. The visiting teacher is a teacher who has had training in social work. She studies the child to see whether he is getting on as well as possible in all his relationships, at home, in school, in church, in relation to his play, his health, his mental attitude. At present it is the children who are not getting along well who are referred to the visiting teacher, but in time let us hope that the child who has not shown any signs of trouble will be studied to make sure that his development is proceeding as well as possible, and to prevent trouble. It seems to be of the greatest importance that these social workers in the schools should be well grounded in mental hygiene. It may be that among a staff of visiting teachers one or more should have special psychiatric training to deal with the extreme cases of behavior difficulty, but certainly every one on the staff will need to know a good deal about psychiatry. There is an unlimited opportunity for the visiting teacher to instruct parents in mental hygiene principles.

There has recently been a movement for mental hygiene of industry. Within the last five years there has been a good deal said on the subject; a number of papers have been written, some speeches made and a few studies undertaken. So far, I know of no industrial plant that has been bold enough to establish a psychiatric department—the name is too terrifying to be faced. The suggestion made by Dr. E. E. Southard was a mental hygiene working party to study the needs of a plant and consider how mental hygiene might be applied to promote the welfare and efficiency of all there is engaged in it for the executive staff as well as the employes should receive its benefits. In one plant that I visited the head of the medical department was planning to examine all of the executive staff with the idea of maintaining their efficiency and he said he would like to have a psychiatric examination go along with the physical examination.

### A Working Crew

The mental hygiene working party would consist of a psychiatrist, a psychologist and a social worker. They would study the plant carefully and find out how in that particular industrial organization their services could be used with benefit. The way to go about it can not be stated as a general proposition but must be worked out carefully in a concrete situation under practical conditions.

This recommendation of Dr. Southard's was the result of a study of the mental hygiene of industry that he undertook with my assistance for the Engineering Foundation in 1919. This investigation came to an end after Dr. Southard's death the following year. He had written three papers on the subject, and in a report given at the National Conference of Social Work I summed up what we had done. The reason for our being engaged in such a study was the belief that through mental hygiene many employees might be kept fit who would otherwise lose their jobs and that others who were not doing their best work might become more productive. This belief dawned upon us as we saw the results of social work at the Boston Psychopathic Hospital in keeping at work psychopathic employees who came there for treatment. It was clear that there were many such employed in industry who never came to a hospital but got discharged and then down and out; and also that the same principles of mental hygiene that kept sick men at work would

keep well men from getting sick and make half-well men more fit. A little understanding of an employee's mental state by the employer or the foreman may result in great benefit to the firm and the workman. A man subject to spells of restlessness and excitement, when he was unfit to work, was an expert workman and so valuable that his firm said they would gladly give him two weeks off now and then when he needed it and also protect him from overtime work. Once, when I was showing some charts of cases treated at the Psychopathic Hospital to the owner of a mill in a small town, he said, "I discharged a man yesterday who was probably of that sort. If I had known this I would not have discharged him."

In considering the mental hygiene of the workman, not only his working conditions, but his home conditions and his personal habits must be reckoned with. Any sort of social disorder is likely to interfere with a man's working capacity. When a man is not getting on in his work as well as he should it is time to look into his other relationships and see what can be done to improve his total social adjustment.

A young woman, a typesetter, was brought to the Psychopathic Hospital after an attempt at suicide. For some time her work had been falling off, until she had gotten down to a job that did not pay her a living wage. The doctors said she was not suffering from mental disease and that she was an intelligent girl, that her trouble was a defect in emotional stability, and she needed more variety in her life. She had left home, leaving the support of her invalid mother to her sister, she had been drinking, she told scandalous stories about her clergyman and others until she was so unpopular that her former friends avoided her, and she was physically sick. Unhappy and discouraged, and unable to straighten herself out, she acted upon an impulse to end her life and drank some Paris Green. With the help of a social worker, this girl recovered to such an extent that she very soon found herself a good job at typesetting where she was quickly advanced.

The advice and assistance of a social worker will be resented by an employee,—or anybody else,—if it is offered in a clumsy or mechanical way and without understanding, but it is the business of the trained social worker to offer his services in a way to make them acceptable. Preventive social treatment cannot be given to an unwilling patient. The social

worker must know how to arouse the patient's desire to do what is necessary to improve his condition.

In conclusion, social work in relation to the mental hygiene of the individual has two aspects. The first is the necessity for psychiatric social workers trained to assist psychiatrists in the care of mental cases. This is now generally recognized and the need now is for more trained psychiatric social workers. The second aspect of the subject is the opportunity that all social workers have to promote mental hygiene. Theoretically this is now fairly well known and many social workers are seeking instruction in mental hygiene. In the new fields in which social work is opening up, industry and the schools, it is to be hoped and to be expected that the mental hygiene point of view will prevail.

### Penalties of the Late Discovery of Tuberculosis

Certain medical results brought out by the Framingham Community Health and Tuberculosis Demonstration are emphasized in a recent communication to the *Journal* of the American Medical Association by Drs. D. B. Armstrong and P. C. Bartlett. Among other findings of interest, they enumerate the principal factors which seem to be responsible for the late discovery of tuberculosis cases. Despite the active measures taken for the discovery and treatment of the disease in Framingham, there was also a mortality of about 21 per cent of the 376 individuals cared for during a period of four years. Deducting those cases where death should have been prevented or at least postponed, it is concluded that 17 per cent is the irreducible fatality rate for such a representative group.

Reasons given by Dr. Armstrong for delayed discovery of active cases are: The recluse type, never receiving any medical attention; patients failing to seek medical advice early, or, if they do, not giving the physician sufficient time to make a diagnosis; occasional failure of physicians to detect disease early; failure of both physician and patient to use all of the services at their command for early diagnosis of tuberculous disease; lack of complete annual medical examination, and lack of annual factory and school examinations.

Application of proper measures directed against postponement in diagnosis is destined to bring about an even further reduction in tuberculosis fatality.

# California Investigates Diets

BY ALICE M. HEINZ, A. M., FORMERLY DIETITIAN FOR THE CALIFORNIA STATE BOARD OF CHARITIES AND CORRECTIONS, ARRAYO SANATORIUM, ARRAYO, CAL.

**D**URING the spring of 1918, the California State Board of Charities and Corrections, being anxious to learn whether children in public institutions coming under their jurisdiction were being given adequate diets, undertook a series of investigations into institutional dietaries.

A careful study of the menus of twenty-two children's institutions, followed by a discussion with the superintendent regarding the kind and amount of food furnished, revealed a shortage of practically the same classes of foods in each instance and in the majority of institutions studied, namely, a shortage of those foods necessary for proper growth and nourishment of muscle, bone and nerve tissue, those foods rich in protein, mineral matter, vitamins, and fats.

## Feeding for Growth

Despite the fact that so much has been said and written about milk being a nearly perfect food, especially for the young growing child, only one of the institutions allowed an adequate amount of milk in the daily diet—namely four cupfuls, the equivalent of a quart. Sixteen institutions allowed less than a pint, (two measuring cupfuls) per day, and of these six were guilty of giving only one cupful or less. Seven institutions allowed a pint or more to a child and another furnished three cupfuls.

Feeding experiments have revealed the fact that a growing child requires and utilizes daily as much calcium, of which milk is the chief source, as is contained in a quart of milk. This indicates that in feeding children about a quart of milk should be allowed each child daily in order to insure the amount of calcium necessary for the proper growth and nourishment of both bones and teeth, to retain perfect control of muscles, and to furnish body juices and tissues with a necessary mineral constituent.

Fresh vegetables, fruits, and cereals supplement the calcium content of a diet to some extent, but these are too limited in their calcium content to furnish an adequate amount.

Besides being valuable for its calcium content, milk supplies very digestible forms of protein and fat and is, especially in a raw state, one of

our chief sources of vitamins, now regarded as such important factors in the selections of a proper diet.

Next in importance to milk, come the other necessary protein foods. While these—meat, eggs, fish, and cheese—are interchangeable to a large degree, since they resemble milk in its ability to build muscle tissue, these, too, were found deficient in amounts in the majority of dietaries. Eight institutions served meat daily or almost daily. Eleven served meat three or four times a week. Two institutions served meat two or three times a week. One institution gave no data. The amount of meat allowed per person was not in every case obtainable, but the amount was too small in many instances. One institution gave an adequate amount of meat daily, but in the other homes where the actual figures were obtainable, the average amount of raw meat per person, including waste material, averaged from 3.5 ounces to 1.1 ounce per person per day, on the days when meat was served. One institution in its attempt to economize, gave not only an inadequate amount, namely 1.1 ounce, but an extremely poor choice also, choosing liver, heart, and wienerwurst as a weekly diet and a prepared meat loaf, bought at a delicatessen shop, as a Sunday feast.

As a rule, eggs were used for cooking purposes only, and very sparingly, too. One institution served eggs every other day. Two institutions served eggs twice weekly. About seven institutions served eggs occasionally. Cheese was used sparingly in almost every institution. Two institutions used macaroni and cheese as the chief substitute for meat, a really excellent substitute. Four institutions served cheese about once a week, but the remaining institutions served cheese only occasionally, or not at all.

Beans seemed to be the chief meat substitute, due partly to the fact that they are less expensive than eggs, fish, cheese, and milk, and partly because beans were formerly held in high repute as a meat substitute. Recent experiments have shown that the protein or tissue building substance contained in beans is greatly inferior to that of meat, eggs, milk, fish, and cheese. In addition to this, since beans are difficult of digestion, it is not advisable to include them three

times weekly in the dietary of children, as was found to be the case in some institutions.

Fat, which is essential in a child's dietary because the proper growth and development of all nerve and brain tissue and bone marrow are dependent upon its presence, was found too low in many of the diets. Six of the institutions were serving no butter at all. In some cases oleo was served in its place, but even this was given but once a day in a number of institutions. Three institutions served neither butter nor oleo, using either peanut oil, peanut butter, jam, or syrup as substitute. Three institutions served butter once to twice a week. Five institutions served butter once a day. Three institutions served butter twice a day.

## Serious Butter Deficiency

This matter of the deficiency of butter in the diet would not be of such importance if it were not for the fact that other fats, such as are furnished by an adequate amount of milk, salad dressing, meats, eggs, and chocolate, were low or lacking, also. Butter substitutes made of vegetable fats are not equivalent to butter in food value, because they do not contain the fat soluble vitamins, which we know to be necessary for growth.

As a rule, most diets furnished enough fruits and green vegetables, especially at the time of the year when the investigations were made and these foods were cheap. Several institutions, however, did not include fruit in the daily diet, while several did not give enough green vegetables. Both fruits and vegetables, particularly the leafy vegetables, supply mineral matter to the diet. Both contain vitamins and also furnish bulk to the diet. It is essential that both should be included in the daily diet.

These studies were made at a time when food supplies were soaring in price and it was found necessary in practically all institutions to curtail expenses, since the allowance for maintenance for these orphan children was really inadequate; however, it also brought out quite clearly the fact that there was a general lack of knowledge of foods and food values and it was largely due to this ignorance that these poor selections were made.

## Camp Wildwood a Stimulus for Boys

WITH the coming of Spring one's thoughts turn to the outdoors; the age-old urge of the open country and woods, man's first home, makes itself felt, and fortunate is the boy who finds expression in a camp such as Camp Wildwood, Rock-

steady blaze, and that green birch was the best wood for open fires.

The camp is located near the natural habitat of the mink and muskrat. Tracks of the wildcat and the skeleton of a deer were found in the vicinity while occasionally a buck

cream, cerise, scarlet, pretzel, olive drab, mahogany, and chocolate. The requirements for admission are usually acquired on the tennis courts and ball field, on mountain trips, and at meetings of the club on the beach after a swim. Trophies of the club are proudly carried home in the fall.

The imagination of the boy is appealed to in the organization of Indian bands, nine in number, each with its chief. The tribes navigate the rapids in canoes, hunt for food, and display the same stoicism in the face of danger as their red-skinned ancestors. Farcical drama gives the thespionic their opportunity while Indian ceremony appeals to the ritualistic. Honors are awarded each year for the three best Indian shirts decorated by the "braves."

But while romance is allowed to filter into the hearts and imaginations of the young campers, utilitarian duties are not neglected. *Fronde Silvestres*, the camp weekly, runs a cookery column setting forth recipes and detailed directions for the making of flapjacks and other camp delicacies. There is also a carpentry shop which trains in manual dexterity and gives the boy a chance to use his ingenuity in construction.

The outdoor stimulus to appetite, the healthful living and wholesome food increased the weight of the boys collectively 534 pounds in one two months' session. Seventy-seven of the eighty-six boys showed an increase in weight, the average being four and one-third pounds. Two boys put on twelve and one-half pounds each.

Senior Baseball team at Camp Wildwood, Kineo, Maine. Organized games play a large part in the camp schedule.

wood, Maine. Directed by Sumner R. Hooper, Harvard '95, the camp is about to enter its eighteenth session.

That experience maketh a full man is the belief of the Camp, and its various activities appeal to many different bents. For the boy who loves nature study there are ornithology, biology, and forestry. Tennis, baseball and swimming attract the lover of sports; Indian bands and amateur plays appeal to the dramatic; while romance is found in trips into the wilds. But "fringers," boys who stand on the sidelines, are not popular at Camp Wildwood, and every one is encouraged to participate in the various types of activity.

The accomplishments of the boys in identifying birds, insects, and trees is notable. Over 110 birds, 48 kinds of butterflies, 31 species of moths, 18 classifications of beetles as well as many other kinds of insects were discovered and identified during one session of the camp. Forty-five varieties of trees were found in the vicinity of the camp. The practical use of wood was also discovered—that dry balsam fir was best to make a fire Indian fashion; that dry cedar was best for starting a fire but too flashy to cook over; that balsam and spruce were inferior to birch and hard woods for a

deer, fawn, and doe have been seen. Young rabbits, ducks, and harmless snakes have become pets of the boys. The Camp is situated on Moosehead Lake on a farm of two hundred acres. The farm furnishes fresh eggs, chickens, lamb, milk, and vegetables for the camp.

One of the organizations is the Browning club, membership in which consists of eight degrees—snow white,

Manual training class at Camp Wildwood, Kineo, Maine.

Councilors averaged a gain of eight pounds; only one showed a reduction, while another gained nineteen pounds.

The routine of the camp is well depicted in a retrospective editorial in the camp publication:

All through the winter months pictures from Sandbar Point will be returning. There will be the recollection of reveille with pajama drill and the morning plunge. We shall see again the dining tent with its long

tables, its mills and "blat," its seconds, and "Plates down!" and finally the clanging bell, and announcements. So it will run through the day, with forestry and first aid, military drill and tennis, and finally the group of boys seated around the piano for the hymns and prayers just before taps.

But before that routine background will rise pictures that have impressed us most during two months here. For some it will be the struggle of the councilors with the wild torrents of

Sam Cole pitch, while those who went to Spencer will see the pond lying quiet in the sunset during the little after-supper fishing trip near the beaver dams. It may be the vista from the summit Kineo, Squaw, or Spencer that stands out most vividly; or it may be the council ring lighted only by the blazing logs, while the hundred braves sit in Indian skins to challenge and to report adventures. A marshmallow roast, or an evening entertainment may be the event that made the deepest impression.

## A Summer Camp for Employed Young People

BY CAPTAIN PERCIVAL CONDIT JONES, ACTING COMMANDANT, JOHN WANAMAKER COMMERCIAL INSTITUTE, PHILADELPHIA, PA.

THE John Wanamaker Commercial Institute of the John Wanamaker Store, Philadelphia, which is composed of the younger employees, boys and girls between the ages of fourteen and eighteen years, organized for educational purposes, has for twenty-three years

"Barracks," which is used as a mess hall, recreation and sleeping quarters, and a smaller building called the "Annex," used for sleeping purposes only. All of the boys live in tents as do also the majority of the girls as they like the novelty of living in the open air. But any who desire to

assemble in the recreation hall for the "amusement hour."

The camp is self-governing, under the supervision of an executive staff. It is policed thoroughly every morning by cadets assigned to that duty; then morning inspection is held to see that each cadet, tent and company street is clean and sanitary. Cadets are taught the proper care of themselves and of the property under their care. Camp sanitation and personal hygiene are given special attention.

The tents are seven by nine feet, each with board floor, cots and kit boxes for personal belongings. A fly (or extra flap) is attached to each tent, making it absolutely water proof. During the day all tent walls must be kept rolled up.

All sports and exercises are under the supervision of the athletic officer; in fact, all the activities are under the supervision of competent authorities.

The camp life is greatly enjoyed by the young people and is eagerly looked forward to from year to year. It greatly benefits the young people to live in the open air and sunshine, with plenty of exercise and good food. They return to business full of enthusiasm and good health, and show greater interest in their work.

Each cadet is required to take part

"The Barracks" used as mess hall, recreation, and administration building, J. W. C. I. Camp, Island Heights, N. J.

maintained a summer camp at Island Heights, N. J., on Barnegat Bay.

The camp is recreational, with physical and military training with discipline.

During the months of July and August the camp is occupied first by the boys and then by the girls. The boys are divided into two groups, each group spending two weeks at the camp; and the girls in like manner.

The camp, consisting of about fourteen acres of land owned by the Wanamaker organization, is located in the healthful pine belt of New Jersey, and combines the seashore and country. It is not far from "Lakewood," the famous winter resort. The parade ground and athletic field are covered with beautiful grass, while the portion of the camp where the tents are pitched is gravel.

There are two buildings on the grounds, a large one known as the

do so have the privilege of sleeping in the Barracks.

Meals are served in the mess hall.

The day is devoted to drills, athletics, body building exercises, swimming, hiking, boating, motoring, and rifle practice.

A parade, in uniform, is held in the early evening, after which the cadets

in some form of athletics. Those who cannot swim are assigned to comrades to be taught.

Athletic contests and military drills between the various companies are held. Points are given for merit and points are taken off for breaches of discipline. Special prizes are given to the winners of the various contests. To each member of the unit showing the greatest efficiency is given a blue bar bearing the word "Efficiency."

One striking feature of the camp is the truck garden where vegetables of various sorts are raised for the table. This makes it possible to serve fresh vegetables where otherwise canned goods would have to be used.

The camp has been pronounced by many prominent military men and

others who have visited it to be a model of its kind.

The following daily routine is carried out by the boys, with some slight modification for the girls.

**BOYS' DAILY ROUTINE**

A.M.	10:00	Swimming call.	
6:45	First call.	10:45	Recall.
6:50	Reveille.		P.M.

## Armour Camp at Round Lake

ON THE banks of Round Lake, a mile and a quarter in diameter and forty-five miles from Chicago, is Oval Lodge, the country home and pleasure resort of the employees of Armour and Company. For the last two years Oval Lodge has been thrown open to employees and their families who desire to spend their vacations in the quiet of the country, yet among friends and acquaintances. At the beginning of the vacation season a schedule is prepared and reservations are made. Fishing and boating, hunting and tramping in the woods, or outdoor sports such as tennis, volley ball, basket ball, and golf are provided for in the parks of Round Lake.

In addition to accommodating one hundred house guests at one time, Oval Lodge has a dance hall, reading room, and screened porches. A matron is in charge at all times, and a trained nurse, whose services may be had should occasion arise, is in constant attendance.

Many of the girls, especially from the general office, take advantage of the recreational opportunities afforded by Round Lake over the week ends

during the summer season. On national holidays such as Decoration Day and the Fourth of July, special programs are arranged at the Lodge.

An effort is made by the office management, under whose supervision the operations of Round Lake fall, to see that every employee has an opportunity to visit the lodge at least once each season, and special holiday programs are usually occasions for individual invitations to some of the members of the organization who have not previously become acquainted with the restfulness of the country home.

Round Lake was purchased by P. D. Armour many years ago before commercial refrigeration had been made practical. The lake was utilized as an ice field and a large ice house was constructed on its shore. When artificial refrigeration came into general use, Round Lake, abandoned as an ice field, lay idle for some time. Several years ago its value as a recreation grounds for employees began to impress itself upon the minds of those responsible for the personnel of Armour and Company. The old ice house was remodeled, changed, and added to until there emerged a comfortable, rambling country lodge. The adjacent land was parked, tennis courts were laid out, boats and bathing suits were provided so that the lake itself might be utilized to its fullest advantage, a nearby golf course was made available, roads were improved for those employees who chose to drive to the lodge, and every convenience available at a modern resort was added so that Oval Lodge might become a real recreation center.

Oval Lodge at Round Lake, Ill., recreation camp for Armour and Company employees. Utilized as an ice field before commercial refrigeration became practical, Round Lake has now become a center of social activity and the old ice house remodeled has become a rambling country lodge.

## Iowa State Juvenile Home

THE vicissitudes of establishing a State Juvenile Home are entertainingly told by A. E. Kepford, Superintendent of the Iowa State Juvenile Home at Toledo, Ia., in the *Iowa Bulletin of State Institutions*. The matter of getting the buildings into condition, renovating and cleaning them, of buying furniture, food,

the institution hopes to avoid in the future, letters such as it received from the board of control stating "The board and the purchasing agent spent four solid hours in checking and revising your estimates. We are sure it would take a storeroom four times as large as the present storeroom at your institution to house the supplies

According to a recent letter from Dr. Kepford to *THE NATION'S HEALTH* all children upon admission are vaccinated against smallpox unless they can show proof of a recent effective vaccination. They are also given an immunizing dose of one thousand units of antitoxin against diphtheria which has greatly lessened the prevalence of this disease. The Home expects to introduce the Schick method of diphtheria control within a short time.

Dr. A. A. Race, a Toledo physician and overseas veteran, is on the medical staff of the Home. Dr. Royal F. French, eye, ear, nose and throat specialist of Marshalltown, is also a member of the staff. The removal of nose and throat obstructions has been found to aid greatly in the handling of semi-delinquent children. Dr. French is at present making a study of certain chemical re-agents in eye work.

A psychiatric study of the 141 children in the home has been made by Dr. Lawson G. Lowery, assistant director of the State Psychopathic Hospital at Iowa City, and by Dr. John B. Morgan, psychiatrist at the same institution. Their findings have also been valuable in the discipline and direction of the children.

"The State Juvenile Home might properly be called a laboratory of democracy, a sort of an experiment station for the development of citizenship out of some most unpromising material," writes Mr. Kepford in conclusion. "Here the semi-delinquent and frequently the semi-normal child is segregated in an environment approximating home as nearly as an

Playing "leapfrog" at the Iowa State Juvenile Home. Every effort is made to minimize the institutional aspect and to give homeless children a real home.

obtaining cooks, matrons, and assistants all rested on the superintendent. One difficulty was that no funds could be granted to the home until children were actually in residence there. This technicality was overcome by receiving a few days after the opening of the Home a child from Waterloo whose application had been on file.

The struggle to keep cooks, to educate them that all food doesn't grow in cans, and that variety in edibles is a desirable culinary rule was an onerous duty. But with wasteful cooks, slovenly ones, and undependable ones came a few who were conscientious, economical,—some with institutional training. In the early days of the Home when temperamental cooks left without notice, other members of the staff donned aprons and meals were served on time as usual.

Budgets, estimates, items, voucher numbers, reports and revenue statements, balances and invoices, came to be vital words in the superintendent's vocabulary,—not only words but facts. After submitting "supplemental estimates" to the Board of Control as well as reports lacking in the requisite detail, they evolved a system whereby everything used in the State Juvenile Home was to have an item number. With such a system

estimated for, were we to purchase same."

The hiring of assistants also was a problem to the new home. Young women who felt called to work with the young delinquents often lost their ardor when washing dirty little faces was found to be part of the job.

Adequate arrangements have been made for the health of the children in the Iowa State Juvenile Home.

Girls' Cottage, State Juvenile Home, Toledo, Iowa.

institution can do this. Here the state is turning its attention to the sources of citizenship and striving to place the child in the stream of self-government. If the state will take care of the child, the child will take care of the state. This axiom of patriotism can find demonstration in every good American home."

The Iowa State Juvenile Home be-

lieves in the innate goodness of every child. It realizes that many of its charges are helpless, defenseless, neglected, sometimes handicapped by mental deficiency or moral delinquency. It attempts to provide a home where homeless children can gain encouragement and by the proper care and conservation get a new hold on life.

excretes on food or a wound contains multitudes of germs. Some of these find suitable culture media and grow, thus begins the danger that may result in death.

The flies that enter your house may have traveled many miles and come directly from the worst plague spot in the whole community.

## Flies as Food Poisoners\*

THE writer has positive knowledge that a marauder has been prowling around. He belongs to a very large band of secret enemies of mankind who live in the filthiest sections of our cities and country-side and spread out from thence on their death dealing missions. They are not deliberate enemies of our race, but are impelled by the most powerful natural instincts, survival and propagation. They prowl around homes and enter them in search of food and shelter. They know no other right than their own.

They steal food in quantities so small their loss is hardly noticed, but at the time of theft they implant by deliberate acts filth containing often the deadliest diseases, and they are most likely to leave these death dealing germs upon choicest foods. These marauders are deadly enemies of the human race through their very instinctive acts. During the Spanish-American War they were persistent camp followers, and largely through their ravages Camp Chickamauga was decimated by typhoid fever and similar diseases.

During the recent war the writer visited one army camp where the cases of typhoid and dysentery were daily becoming greater and found that practically the only cause was a most aggravated condition of filth inhabited by millions of these deadly marauders, who were everywhere in the camp, especially in the kitchen and mess halls.

The common house fly, *Musca domestica*, is perhaps the deadliest of all human enemies. It breeds in manure and excreta of all kinds, being very fond of stable manure and human offal. It also breeds in garbage and organic waste. It haunts stables, chicken yards, privies, sewers, garbage pails and dumps. It loves to

visit man and animals. A discharge of mucous or pus will attract it to the spot. It is very fond of open sores, and likes to visit unprotected babies and feed around their mouths and eyes and ears. But almost nothing can keep it away from savory foods, once it enters the house.

Science has proved the fly to be a common carrier of many kinds of deadly disease germs, such as typhoid, dysentery, septicemia, ophthalmia, cholera, and anthrax. These germs live for weeks and months in the body of the fly and are deadlier for having so lived. Every drop that the fly

The General Assembly of Virginia passed the following bills proposed by the Children's Code Commission of the state at the close of its last session: A group of bills providing for (a) public relief for children in their own homes to be administered by the local boards of public welfare; (b) regulating child-placing and child-caring institutions and agencies; (c) regulating maternity hospitals; (d) regulating boarding houses and nurseries for children under six years of age. No State appropriation was made for the operation of the mothers' aid law.

The League of Red Cross Societies is moving its headquarters from Geneva to Paris, thereby reducing expenses \$15,000 yearly.

# Eye Clinics Conserve the New York City Child

## Clinics, Under Bureau of Child Hygiene, Coordinate with Schools

BY M. B. BEALS, M.D., SUPERVISING OCULIST, DEPARTMENT OF HEALTH, NEW YORK CITY

THE eye clinics of the Bureau of Child Hygiene, Department of Health, New York City, were organized in 1902, to care for the large number of cases of trachoma and cases of suspected trachoma found at that time in the public schools and for several years the work of these clinics continued to handle almost exclusively the treatment of and operation of these cases. The eye clinics are now nine in number, located, with one exception, in public schools, five in Manhattan, two in Brooklyn, one in the Bronx, and one in Queens, maintained under the jurisdiction and in accordance with the rules and regulations of the State Board of Charities. Only children whose parents are unable to pay a private physician are accepted for treatment. The eye clinics of the Bureau of Child Hygiene have been reorganized during the past three years and there exists a system of close coordination with the Division of School Medical Inspection to produce a great increase in efficiency over the old organization and to produce the following results: (1) the detection and treatment of all contagious eye diseases of school children; (2) the detection and correction of refractive errors of school children not already under private treatment; (3) the examination of all candidates for and the supervision of the Sight Conservation and Blind classes of public schools. The staff consists of:

The Director and Assistant Director of the Bureau of Child Hygiene, in full charge of the clinics of all boroughs.

The Borough Chiefs of each borough in control of the administration of the clinics of each borough.

The Supervising Oculist charged with the supervision of the technical work of the staff of the clinics of all boroughs and in direct charge of the Sight Conservation and Blind Classes.

The Supervising Medical Inspector, field head of the work in schools.

The Supervising Nurses, field head of nurses in clinics and schools.

Oculists and Nurses in each clinic. Medical Inspectors and Nurses in schools.

The character of the work of the

eye clinics has changed greatly in the last three years.

In response to the recognized harmful effects of refractive errors on the mental development of the growing child, the refraction work of the clinics has increased enormously, and the clinics have a highly developed staff of ophthalmologists in refraction of young children, mentally defective children, and partly sighted children.

In the line of experimental research, groups of hundreds of mentally defective children, "habitually left back" children have been refracted, and those with refractive errors have been properly fitted with glasses and the cases followed up for months and years for data on the effects of eye strain on the child mentally.

### The Backward Child

There are several reasons why these clinics are needed in addition to the several large public eye dispensaries of this city.

First: Correct refraction of the young child is a tedious and tiresome task, and in nearly all eye dispensaries the refraction, for this reason, is passed on to the novice or lowest assistant in the clinic, and, in some cases, to the optician who has the contract to fill the prescriptions for the glasses.

Refraction of the very young child, the backward child, and the mentally defective child calls for the very highest skill on the part of the oculist and should never be entrusted to the novice or optician.

The oculists of the Child Hygiene clinics are highly trained oculists with years of experience in refracting these cases.

Second: It has been impossible to obtain sufficient facilities in the public eye clinics of the city to handle the great mass of refraction work.

The Sight Conservation and Blind Classes are under the direct supervision and care of the Supervising Oculist.

All candidates for these classes are examined by an oculist of our clinics and the report sent to the supervising oculist who makes the final recommendation as to the assignment of the

child to a normal, sight conservation or a blind class, and, in those cases not under private treatment, which is the case in the great majority of these children, he assumes the active treatment of the condition of the eyes found, if any treatment is indicated.

### Sight Conservation Classes

A vast amount has been accomplished by this intensive systematic work in the Sight Conservation Classes. About two thousand candidates have been examined. One hundred ten were assigned to the Blind Class, where the blind child is taught the Braille system of finger reading.

Eight hundred and forty-five were assigned to the Sight Conservation Classes which are equipped with special large print books, raised maps, most favorable lighting, individual assistance from a special teacher to permit these partly sighted children to perform as near regular grade work as possible without injury to their already crippled eyes.

All of this class of children, who are not under private treatment, and where it is indicated for the existing condition, are cared for by a cooperative plan between the special teachers of these classes and the supervising oculist of the clinics. In this way it has been possible to accomplish a great amount of improvement in many cases, as, by this cooperation, the child is kept constantly under observation and treatment, which overcome the great obstacle to results in the treatment of this class of cases in public eye clinics with no official connection with the Department of Education.

Results have been particularly shown in the removal of corneal scars, by the prolonged application of negative galvanism; clearing up old trachoma cases, keeping the progressive myopes under constant observation, and closely following their sometimes rapidly changing refractive condition, which are so important in these cases.

The system, now in operation between the eye clinics and the schools, to care for the eye cases without loss of school time to the child, and to avoid confusion and overcrowding at

International Newsreel Corp.

the clinics, is for the school nurse or school principal, teacher, social worker, or attendance officer, to call up the nearest eye clinic by telephone and make an appointment for a certain number of cases on a certain day.

It is required that the parent sign a consent card, and that the parent or some older person accompany the child if a mydriatic is to be used.

The school nurse, social worker, attendance officers, etc., often bring groups of these children to the clinics saving the parents the loss of time from their work or other home duties.

During the year ending July 1, 1920, these clinics did the following work:

Visits to Clinics.....	79,253
New Cases .....	19,639
Refractions .....	30,128
Prescriptions for Glasses..	10,021
Medical Prescriptions given	84,068

The sight conservation work in the public schools is: (1) To provide conditions under which the "partially sighted" children may study without injury to the eyes; (2) to provide supervision and treatment by an oculist of the Bureau of Child Hygiene.

The equipment for these classes consists of special large print, proper light, raised maps, adjustable desks, and individual assistance by the teacher, who prepares all the work in large easily read copy, which permits the partly sighted child to keep pace with its normal grade without further loss of vision.

Constant supervision and treatment are afforded by the oculist of the

Bureau of Child Hygiene of the Department of Health, who examines the eyes of all candidates and assigns the child to a blind, sight conservation or a normal class. He makes a full diagnosis and prognosis and outlines the kind and quantity of work that may be permitted for each individual child. Also effort is made to improve the conditions found, by indicated treatment, whatever be the condition, disease or refractive error.

Each child suffering from any eye disease or refractive error is instructed to go to its private oculist for treatment, if financially able, but with the great majority of children in these classes this is not the case, in which event, if the parents consent, the child is treated in the Child Hygiene Special Clinic for these classes.

The oculist's care of these classes has been under the direction of the Bureau of Child Hygiene of the Department of Health for about six years, with most gratifying results in a large number of cases. The hearty cooperation of Miss Moscrip, the inspector of the blind and sight conservation classes, and her splendid corps of teachers has been of great assistance. The blind classes continue to teach the Braille method and other usual educational work for the blind. At present there are six blind classes and twenty-eight sight conservation classes.

Some highly practical results have been obtained since the Bureau of Child Hygiene took over this work—results that would not have been obtained, if we had not taken over this work—as, for example, through the combined efforts of principals, teachers, medical inspectors and nurses after special instructions by the supervising oculist a large number of children with a vision in the better eye of 20/70 or worse, were found, taken to our clinics, and hundreds were returned to school with practically normal vision after treatment or refraction. These children had nearly all been through the usual routine of medical school inspection, but due to defects somewhere in the system—either in the original vision test, follow-up work, or a lack of cooperation by principals and teachers, due, in most cases, to a lack of a thorough understanding of the importance of this work, there had been failure to get them under proper treatment.

Of those admitted to the Sight Conservation Classes with a vision that could not be improved at once by refraction sufficiently to do normal work, many have been improved by

International Newsreel Corp.

The eyes of all school children are examined and those suffering from defective vision are assigned to eyesight conservation classes which are equipped with special large print books, raised maps, and excellent lighting systems.

combined treatment and proper use of eyes to such a degree that they have been reassigned to normal classes.

All children with a vision in the better eye of 20/70 or worse are candidates for the sight conservation class. If the service of the oculist cannot improve this vision, the child may be assigned to the sight conservation class. If the vision is improved to better than 20/50 by glasses or treatment, the oculist decides if sight conservation work would be beneficial in each case, as in many cases of progressive myopia the vision can be improved with glasses to a greater degree than 20/30 or even normal vision, 20/20.

A final recommendation is given by the oculist in charge of each case as to the use of eyes to be permitted, with full instructions as to glasses, revisits to the oculist, etc., as by this method only can most children be kept under most favorable conditions.

The educational feature of the work of the eye clinics is becoming more and more prominent not only with the parents and children and teachers of the sight conservation classes, but with principals and teachers throughout the city, many principals today have but a very vague idea of what a sight conservation class is, but nearly all are intensely interested and cooperative after hearing the subject fully explained with the other very important activities of the eye clinics, especially the subject of the harmful effects of refractive errors on the mentality of the growing child.

By far the most common causes of

loss of vision by the children of the sight conservation classes is progressive myopia. Progressive myopia is a subject with which the general practitioner and the school teacher should be far more familiar with than many now are. They should be sufficiently familiar with this subject to be able to explain intelligently to parents and children why the myopic eye needs so much more careful and constant attention than other forms of refractive errors.

It is here that the sight conservation class is of inestimable value in cooperating with the oculist in saving these near-sighted children from irreparable injury to their vision.

The constant strain of the near-sighted eye can be relieved by wearing glasses, if the glasses are properly fitted, combined with the proper use of the eyes, but it is only by the cooperation of the family physician, teacher, social worker, and school nurse that the parents and children can be educated up to the point of giving their eyes proper and sufficiently sustained care.

It is clearly explained to the parents in nontechnical language the ciliary muscle spasm of myopic eyes of children, and, therefore, the necessity for the use of a mydriatic in the proper refraction of these cases and it is thus made clear to them why the child should be taken to the experienced oculist and not to the optician, who, under the law, is not permitted to use a mydriatic because he is not a physician.

Those having control of children of school age should know the importance of proper light and the harm done by working the growing eye in improper light. The starting of near-sight in a normal eye is undoubtedly very often caused by the eye strain necessary to read and study in a poor light.

The question of light received but scant consideration in our schools. I have seen many class-rooms lighted very badly by gas on all days but the very brightest, and the study room of one of our high schools in the auditorium having practically no daylight. No more favorable setting could be imagined for the development of myopia, blepharitis, headaches, and all that long list of neuroses caused by eye strain in the growing child.

It will be necessary to do a great deal of educational and propaganda work before we shall be able to correct these defects in our schools and guard against repetitions in new buildings. Many of the schools used

for night schools are not provided with proper lighting equipment, and the work done in these schools by the pupils under this poor illumination is producing the same bad results as in the poorly lighted day schools.

A large part of the good results of the work of the Sight Conservation Clinic is obtained by skillful refraction, which is the fitting of glasses.

Refraction of the partly sighted child, the mentally defective, backward, or very young children requires the highest skill of the experienced oculist and is wholly beyond the skill of the oculist of little experience and of the optician. This work calls for the constant use of "skiascopy" or the "shadow test" by which the measurement of the refraction of the eye is made without any assistance from the child, as in these classes of children the child can be of but very doubtful assistance to the oculist. After considerable practice a high degree of accuracy is obtained by this method of refraction.

A great deal of harm may be done to defective eyes by their improper use and harm may be done to the physical well being of the child from the effects of eye strain in producing reflex nervous symptoms.

Out of 132 ungraded or mentally defective children whom I refracted, and for whom the glasses were procured, twenty-four were found to be normal mentally after relieving their eye strain and giving them improved vision, and more than 65 per cent showed decided mental improvement, and many showed physical improvement.

On the child of normal mentality defective vision is a great handicap as is shown in every large school or group of schools. In a group of four hundred "habitual left back" children found in a large New York school, more than one hundred showed decided refractive errors and I prescribed glasses for about 110. One hundred of this number procured the glasses, and in less than three months some very pleasing results were obtained. Out of the one hundred more than 98 of the "habitual left backs" passed the regular school examination, many skipping classes, and one boy far behind his grade for age, skipped five grades on the examination. Of the ten who did not have their prescription for the glasses filled, only one was promoted. In the same school we had the walls of a small room nearly covered with test papers showing the startling improvements made in writing, drawing, and

arithmetic in remarkably short periods by the children of all ages after correction of refractive errors.

### Vitamines and Nutrition

The essential nature of the vitamine content of the diet is now generally conceded, and agreement reached in regard to the classification of vitamines, but another point often overlooked is that there needs to be maintained a suitable relationship between the vitamine content and the other dietary constituents, states Dr. M. J. Lewi in the *New York Medical Journal*. The preparation of foods in order that their vitamine content may remain unimpaired, safeguards as to deterioration through aging, and deficiency of vitamines because of food habits or idiosyncrasies or improper combinations, are all to be considered.

Lewi suggests that a number of indefinite complaints of infants and adults may be due to a partly deficient diet and the remedy lie in the administration of vitamines. There is, therefore, a definite place in medicine for some preparation that will contain the vitamines in concentrated form, for co-operation on the part of the pure chemist to determine standards of purity, and to make observations regarding the physiologic effects of the isolated vitamine which may differ from those observed in connection with the naturally occurring food-stuffs.

### A Tip for Girl Hikers

Underwood & Underwood.

Wear both silk hose and woolen ones when hiking is the advice of Miss Nell Creer, photographed at the end of a day's tramping through Zion National Park, Utah. Wear silk hose next the skin; then heavy golf stockings of pure wool—keep them clean and unwrinkled is the formula that might well be followed by all feminine travelers of the road.

# Fighting Malnutrition in Iowa Rural Schools

## The Hot Lunch Affords Good Means of Supplying Children the Proper Foods

By AMY L. DANIELS, Ph.D., CHILD WELFARE RESEARCH STATION, UNIVERSITY OF IOWA, IOWA CITY, IA

**I**N THE first selective draft 28 per cent of all the men called were rejected as unfit to bear arms. Many were underweight; many showed signs of undernourishment; others were suffering from defects which should have been corrected in child-

school children shows that 20 per cent of the city children are seriously under-weight while in the rural schools 30 per cent of the pupils are in this classification.

### Causes of Malnutrition

Faulty home and school hygiene, infections, diseased teeth and tonsils, and enlarged adenoids are common causes of undernutrition among children. The most frequent cause of malnutrition, however, is improper food, sometimes too little, but more frequently too little of the right kind. Children suffering from undernourishment come from the ranks of the well-to-do as often as from among the poor. Underweight in the child should always be the signal for examination by a competent physician.

An adequate diet for the child should include at least three-fourths

Other food habits of the child should also be watched, such as eating too rapidly; drinking water to wash down imperfectly chewed food; lunching between meals. Not enough sleep and not sleeping with open windows hastens the vicious circle of malnutrition.

Children grow from small individuals to large ones and their rate of growth is largely dependent upon the kind and amount of food they take. They need, therefore, foods which supply material for bone, muscles, nerves, and energy. Growing boys of fifteen often consume very nearly twice the amount of food their fathers need.

### Children Need Warm Meals

The kind of food which school children of different ages require varies little, and only in proportion to their size and the amount of exercise they take. School children need three

Children need three warm meals a day.

hood. A large number of these might have been avoided if proper precautions had been taken.

Statistics gathered recently in New York City showed that at least one-third of the children in the public schools were so much below the normal standard of growth as to call for special nutritional care. Recent reports concerning the conditions of children in the country schools of Iowa indicate that they are no more physically fit than their city cousins.

A country nurse found twenty-three out of a class of twenty-nine more than 10 per cent below weight while another report from a rural school stated that all were over 10 per cent below standard. A recent summary of reports on more than 110,000 Iowa

The supplementary hot dish in the rural school.

of a quart of milk a day; some foods which supply iron, such as prunes, spinach, chard, eggs, oatmeal, dried beans, peas, lentils; fruits or vegetables at each meal to supply bulk and certain of the vitamins and the mineral material needed for building bones and other body tissues; it should include also protein, present in eggs, milk, cheese, fish, meat, dried beans, and peas; energy giving foods, such as butter and other animal and vegetable fats; starch, found in bread, cereals, potatoes, and macaroni; and sugar, found in dried fruits, honey, and cane sugar.

warm meals a day. The food required should be evenly distributed among the three meals, one third of the protein and one third of the energy material being given at each meal.

The problem of supplying proper food at noon to the children in the rural schools is especially difficult as most of the pupils live too far to go home for lunch, have had early breakfasts, and have walked or ridden long distances. Their lunches, packed at home, must of necessity be cold and are often dry, lacking vegetables and milk because of the inconvenience in packing them.

No child should be allowed to go to school without an adequate breakfast.

Great care should be taken in packing the lunch box that it be attractive to the child's appetite. The box should be one that is easily cleaned. Most children prefer the folding box or a small pasteboard one that may be thrown away. The lunch boxes should be kept not too near the stove or register nor in a place where the food will freeze in winter. A shelf with a drop curtain makes a satisfactory arrangement. Wrapping each article of food in oiled paper keeps it in palatable condition. Variety may be introduced in the filling of sandwiches and by substituting for cookies or cake, baked custards, puddings, and preserves which may be safely transported in small glass jars with a screw top.

To supply the vegetables and the milk in the school lunch is the purpose of the hot dish in the rural school. The dishes suggested are so simple that pupils of the upper classes may do all the work involved with but little instruction from the teacher. Older girls may also act as waitresses.

Menus such as the following require only a little time to prepare and are comparatively inexpensive:

- 1 coal oil stove
- 1 portable oven
- 1 aluminum or granite kettle, 8-quart
- 1 saucepan
- 1 saucepan, 2-quart
- 1 double boiler, 6-quart
- 4 white enameled bowls
- 2 2-quart
- 1 5-quart
- 1 pint
- 1 ladle, long handle, holding one cup
- 4 spoons
- 2 tablespoons
- 2 teaspoons
- 1 meat grinder
- 3 knives

- 1 butcher
- 2 paring
- 2 forks
- 1 small
- 1 large
- 2 strainers
- 1 puree
- 1 colander
- 1 wooden spoon
- 1 scrubbing brush
- 1 can opener
- 2 baking dishes, 3-quart
- 1 dipper
- 1 tea kettle
- 1 water pail
- 2 trays
- 6 dish towels
- 2 dish cloths

- 1 "mystic mit"
- 1 dish mop
- 2 dish pans
- 1 dish drainer
- 24 cups and saucers
- 24 soup bowls
- 24 serving plates
- 24 soup spoons
- 24 teaspoons
- 24 forks
- 1 quart measure
- 1 asbestos mat
- 1 Dover egg beater
- 1 measuring cup
- 1 wire potato masher
- 1 fireless cooker
- 6 packages paper napkins (500 each)

The equipment for the noon-day home but less confusion will result if lunch will vary with the type of all dishes are owned by the school.

Serving the hot dish.

Week	Monday	Tuesday	Wednesday	Thursday	Friday
I.....	Cocoa	Cream of bean soup	Scotch broth	Cream celery soup	Scalloped corn
II.....	Cream potato soup	Scalloped rice and cheese	Scalloped potatoes	Vegetable soup	Fish chowder
III....	Cream corn soup	Cream of chicken soup	Cocoa	Cream spinach soup	Corn meal or rice or hominy with milk
IV.....	Cream tomato soup	Delmonico potatoes	Cream pea soup	Salmon soup	Corn chowder

The foregoing menus require weekly supplies as listed below:

school. The individual equipment, bowl, cup and saucer may be brought from

Week I	Week II	Week III	Week IV
14 quarts milk	10 quarts milk	6½ quarts milk	15 quarts milk
2 cups fat (drippings, butter or butter substitute)	2 cups beef drippings, butter or butter substitute	1 cup butter or butter substitute	2 cups butter or butter substitute
4 lbs. mutton or beef from neck	6 lbs. white fleshed fish or	1 bunch celery	3 cans salmon
1½ bunches celery	2 lbs. salt cod	3 carrots	1 lb. cheese
4 carrots	1 lb. cheese	2 medium sized onions	5 onions
4 medium sized onions	1 bunch celery	2 cans corn (No. 2)	3 cups bread crumbs
2 cups bread crumbs	6 medium sized onions	1½ cups flour	2½ cups flour
3 cans corn (No. 2)	2 cups bread crumbs	2 tsp. salt	½ lb. salt pork
4 turnips	1 lb. turnips	½ tsp. pepper	5 tsp. salt
1 cup flour	2½ cups flour	2 qts. cream or top milk	1 tsp. pepper
4 tbsp. salt	1 lb. salt pork (No. 2)	2 cans spinach (No. 2)	2 cans tomatoes (No. 2)
1 tsp. pepper	5 tbsp. salt	6 qts. fresh spinach	4 cans peas (No. 2)
6 eggs	½ tsp. pepper	1 lb. dates, figs or prunes	2 tbsp. sugar
3 cups dried beans	40 medium sized potatoes	6 cups rolled oats	26 medium sized potatoes
1 cup pearl barley	1 bunch parsley	1 cup cocoa	½ tsp. soda
1½ tsp. soda	3 cups rice	1 cup sugar	
1 cup sugar			
1 cup cocoa			

The articles listed above have been found to be necessary to equip a school serving twenty-four children.

That the children should pay a small sum, enough to defray the cost of the material used in the hot dish, has been suggested as one means of financing the project. Other suggestions are that the school or some local organization pay the expenses. But as food is more plentiful than pennies in the country homes, the most feasible plan seems to be that of having the children bring the food from home, each home in turn being responsible for one meal.

Teaching the children how to eat is often quite as important as serving the improper food. Order and cleanliness can be taught the children. Hands should be washed before lunch; the dishes should be arranged in an orderly manner on a paper napkin on the desk. A certain amount of freedom should be allowed the children and a happy atmosphere encouraged.

Though the hot noon-day lunch may increase the school budget, it will decrease the cost of education for there will be fewer failures and fewer children repeating grades, and the benefits to the children both mentally and physically far outweigh the cost and trouble in preparing it.

## Medical Excuses from Physical Training

In an effort to secure the cooperation of physicians and limit the needless excuses of students from physical training, Dr. C. Ward Crampton, director of physical training in the New York City schools, has devised a form on which the physician may recommend exercises which will be beneficial for certain conditions, may recommend that certain exercises be omitted, and that others be done with care.

The blank has proved of great service to the physical training department and of benefit to the pupils. Many physicians do not realize that exercise is and should be given to every ambulant cardiac case, states Dr. Crampton, nor do they realize that it is beneficial to the great majority of asthenic conditions that are more or less pathological and common to adolescents. Dr. Crampton found that in New York City many high school students, principally girls, brought excuses from physicians requesting relief from physical training. By means of letters of explanation to family physicians, the physical training director was able to gain their cooperation.

The form letter which is addressed to the director of physical training and signed by the student's physician is a request that physical training exercises be adjusted to suit the condition of the student, the diagnosis being stated.

## Diathermy in Medicine and Surgery

Diathermy is a descriptive term applied to a form of high-frequency electric current which generates a heat that is distributed through (dia) the tissues and not localized to the skin surface. It has been in use only since 1907. Special apparatus is necessary. Diathermy, according to the author, Elkin P. Cumberbatch, is applied medically to stimulate physiological activity, relieve neuritis and benefit high blood pressure. Surgically, diathermy is used to destroy diseased tissue and new growths by a process of coagulation. Cumberbatch describes many instances and illustrates cases where diathermy is used as the complete treatment. In America, however, diathermy or electrothermic-coagulation has been used in conjunction with radiotherapy and surgery. To those who may not be familiar with the identity of the

author, it may be stated that Cumberbatch is an English authority upon Medical Electricity and is one of the editors of the *Journal of Radiology and Electro-Therapy*, the standard English publication. He is the successor of Dr. Lewis Jones at St. Bartholomew's Hospital in London.

"Diathermy, Its Production and Uses in Medicine and Surgery" is the collection, with additions, of a series of papers published in the above mentioned English Journal. A careful reading of the text proves the serious purpose of the author to record his experimental work with diathermy upon tissues and diseases. The limi-

tations imposed upon the method are healthy acknowledgements of its values when intelligently applied.

There has been much confusion among medical readers in America, and possibly mistaken notions among electro-therapists, upon the identity of diathermy. They may think that D'Arsonval current or high-frequency currents or fulguration or hot-sparks were the aliases of diathermy.

Therefore to classify matters, electrically speaking, it may be well to indulge in the clear exposition of diathermy which Cumberbatch affords in this monograph.

C. V. Mosby Company, St. Louis, 1921.

## Paper Toys for Sick Children

FURNISHING entertainment to convalescent children in hospitals is often a problem to the nurse who must devote her time not to one child alone but to many. Ordinary playthings are too heavy for weak little hands, are unhygienic, or, as in communicable disease cases, must be destroyed. At such a time the newspaper comes into its own as material from which fascinating toys of every description can be made. Bakers' and soldiers' caps, trench headgear, and sunbonnets are easily constructed from old newspapers and, like the magic caps of the fairy tales, project their wearers into a make-believe world. Sun hats and sunbonnets which protect the sensitive eyes of the sick child, are also easily made under the direction of mother or nurse.

The newspaper doll family is multitudinous and varied. Captain January, a "newspaper" man, has amused many a sick child. The News family is indeterminate in number, but Mother, Father, and Baby News are well known members. All these little people have pleasant faces for the sick child dislikes ugly, cross expressions. Paper dolls are especially suitable as companions for children in isolation hospitals or confined to their homes with contagious diseases for they can be burned every day and replaced at low cost by new ones.

A brown paper bag has endless possibilities for the amusement of the sick child. A mask that slips over the head can be made by cutting big slashes for the eyes and nose. Shopping bags were made by a group of ward children as a surprise for their mothers who were coming

to see them during visitors' hour. Not content with furnishing the purses, the children cut out money. Small, round discs meant coins to them and very few asked for pencils to mark their denomination.

A graphophone was made from a paper bag by a Junior nurse. Beds, chairs, houses, stores, garages, rocking horses, refrigerators, fireless cookers, and many other unique articles for the doll's house were made by a class of junior nurses under the direction of Mrs. Mary Barker, Supervisor of Kindergartens, Worcester, Mass. This class submitted original models ranging from a circus wagon with a tiger behind the paper bars to dainty open-work boxes for handkerchiefs and gloves. A student nurse submitted a bungalow set in a garden with tiny barn, henhouse, walks, and driveway, all surrounded with a garden fence. So perfect was it in detail that it resembled an architect's model. Paper fans made of newspaper pleated and tied at one end are light and easy for the sick child to use.

Somehow these absurd toys strongly appeal to children. A first grade teacher in the Worcester Public Schools, who gave a lesson on the method of making a newspaper doll, claims that the reactions have been most interesting. Dolls made of newspaper, handbills, tissue and wrapping paper, and wall paper have poured into her school room. Some were dressed in paper, some in cloth, some in lace. To that wise first grade teacher, the intrinsic value was in the effort and imagination that had been put into the making of the doll by a six-year-old child.

## Electrical Injuries

THE increasing casualties resulting from the advance in the use of electricity, show the need for a study of prophylaxis of electrical injuries, comments the *Lancet* in a recent issue. Since 1903 such accidents have been notifiable in Switzerland and figures show that in 1920 the number of injuries from electrical causes had doubled. The incidence, however, has not increased in relation to increased electrical installations.

Classification of electric current into "strong" and "weak" according to their action on the human body is considered by Jaeger to be fallacious, as the danger to life depends upon many other factors. Fatal cases have been reported in the German literature from the therapeutic application of a sinusoidal alternating current of fifty volts or under. Besides the strength, frequency, and nature of the current, and the resistance opposed to it, the danger of any particular current is influenced by the following factors: (1) the site of entrance into the body; (2) the duration of the contact; (3) the size of the area under contact; (4) the physical condition of the individual (status lymphaticus increases the susceptibility); and (5) the psychic component. Expectation of a current diminishes its effect, while surprise increases it.

Were it not for the isolation afforded by the skin, the human body would be a good conductor of electricity owing to its fluid and salt content, he points out. The resistance of the skin varies with its thickness and dryness.

Meteorological conditions have great effect on the number of electrical accidents. Nearly twice as many occur during the hot months of the year as during the cold. Excluding those caused by lightning, the explanation is apparently to be found in the increased formation of perspiration in the summer months. Jaeger considers it unfortunate that even in the latest text books it is stated that 100 to 150 volts are harmless while those of 200 and over are dangerous. Cases of death from currents of 50 volts have been recorded under conditions of dampness.

Expectancy of shock decreases susceptibility while surprise increases it. An example of this was an engine driver who would catch hold of a 500 volt clamp with both hands and let go again as a bet for a glass of beer.

As often as the beer was forthcoming he repeated this game without harm, but one day he came accidentally into contact with the clamp under the same conditions and was killed.

The clinical aspects of electrical injuries are characterized by great variability in their immediate symptoms, in their course, and in their late effects. The immediate effects can be divided into general, local, and distant. "Electric shock" according to Jaeger "is associated with unconsciousness of variable duration which simulates concussion and is often followed by a maniacal stage of cerebral irritation. This condition may occur even when the current did not pass through the central nervous system and is probably reflex in origin. The local effects consist chiefly in burns at the sites of entrance and exit of the current. The lesions are characterized by anemia, dryness, and insensitiveness due to massive coagulation necrosis. Subcutaneous emphysema has often been noted but the cause of its production is not clear. Shedding of the superficial layers of the skin is common, but is not comparable with that produced by ordinary burns. The skin comes off as a complete layer with the hair, attached to the conductor which produced the shock or hanging to the

clothes covering the part. . . . Sometimes the internal organs, heart, and kidneys suffer, the affection probably being due to toxemia as in ordinary burns."

Extending necrosis plays an important part among the late effects, the writer points out, the primary necrosis extending in area and depth and not infrequently attacking the underlying vessels.

In regard to prophylaxis for electrical injuries, the Paris Academy of Medicine has issued the following warnings: (1) Never touch any part of an electric lighting or heating apparatus with wet hands; (2) never handle any part of an electric lighting or heating apparatus while touching water taps or pipes or any other metal which will make a good contact with earth; (3) fix electric fittings as far as possible away from water fittings.

### Michigan Improves Laboratory Service

The Bureau of Laboratories in the State of Michigan averaged thirty-four specimens to every physician in the state during the past year and increased laboratory service throughout the state is planned for the ensuing year.

"The new laboratory will not be surpassed by any state laboratory in the country," declares Dr. R. M. Olin.

### Narcotics from Many Nations

Keystone View Company.

Some of the dope confiscated from smugglers by the Narcotic Division of the U. S. Custom Service in New York City. The little phials at the left contain German cocaine; the bag of envelopes contains German heroin for Italian trade; the small round bottles contain Japanese morphine; the big chunks are raw opium from Asia Minor; in the background on the box is a Chinese opium layout; the small toys are of Chinese prepared opium; then comes Hash Kesh from India; the square cans and bottles contain American heroin, cocaine and morphine; next is the English morphine, while the small pill boxes contain American cocaine and morphine which the illicit drug stores trade on fake doctor's prescriptions.

## Passing Fads in the Manufacture of Dentifrices

*Not a Medicated Dentifrice.* Years ago Colgate & Company refused to meet the artificial demands for a highly medicated dentifrice. They followed scientific dentists in the contention that drugs are harmful to the mucous membrane of the mouth. Such drugs should not be used in a dentifrice except in the treatment of pathological conditions, and then only under the advice of a dental practitioner.

*Not an Acid Dentifrice.* Once more Colgate & Company's stand is with the scientific members of the medical and dental profession who refuse to use an acid tooth paste. They recommend to their patients a dentifrice with high cleansing qualities, pleasant to taste, containing a thorough non-gritty cleanser.

A generous supply of samples will be sent to professional friends, post-paid, on request.

# Sanitation in National Parks

IN VIEW of the great danger of the spread of disease to all States through the hundreds of thousands of persons who visit the national parks annually and the lack of adequate sanitary facilities and medical attention in the park, the bureau upon the request of the Secretary of the Interior in the latter part of the fiscal year undertook to assist the National Park Service in providing the necessary medical attention and to improve the sanitary conditions in the parks in accordance with investigations made by service engineers.

The field work was placed in charge of Associate Sanitary Engineer H. B. Hommon and Junior Assistant Sanitary Engineers A. P. Miller and L. D. Mars, assistants, Acting Assistant Surgeon W. E. Crawbuck was assigned to Yellowstone National Park to furnish the needed medical attention and to carry out certain sanitary inspections. A conference was held with the superintendent of the Sequoia National Park in regard to increasing the existing water supply, improving the sanitary condition of the privies and the collection of garbage. As a result, garbage cans and a regular garbage collecting system will be installed, privy vaults will be disinfected with a spraying machine using cresol, and the water supply will be increased by constructing a dam across the creek which is the present source. Storage tanks will also be built at the main camp to collect and store water during the night.

A large scale map of the main camp grounds was prepared by Junior Assistant Sanitary Engineer Mars for the use of park officials in locating campers during the summer. This will also be used in laying out a sewerage system and a disposal plant.

At Yellowstone National Park samples of water from the main sources were analyzed by the service engineers in a laboratory set up by them. As soon as the examination of the water supplies was completed a detailed sanitary survey of the hotels and camps in the park was made and a report prepared. It was found that the water supplies at the beginning of the season were, as a rule, satisfactory, but that the disposal of sewage from the hotels was very unsatisfactory; that the privies of the Yellowstone Camp Company and in the Government automobile camps were very unsatisfactory; that the mosquitoes

were so numerous and active that visitors were glad to get out of the park; that the garbage in the Government automobile camps should be collected in cans and properly disposed of; and, finally, that a thorough inspection of all places serving food or drinks to either visitors or employees in the park should be made at least every two weeks.

The detailed work to be accomplished by Junior Assistant Sanitary Engineer Miller in Yellowstone National Park during the summer is as follows: (1) Prepare plans and estimates for sewerage systems and disposal plant for Government camps, Yellowstone Camp Company and Yellowstone Hotel Company at Old Faithful Junction. (2) Assist Yellowstone Hotel Company in laying out a new sewer for their Lake Hotel and obtain necessary data for designing disposal plant, including sterilizing apparatus. (3) Measure sewage flow from Lake and Canyon Hotels to determine the capacity of sewage-treatment plants for these places and others of a similar character in the park. (4) Collect a second series of samples from all the water supplies in the park in July, and again in August if time permits. (5) Prepare estimates and plans for mosquito eradication at the hotels and camps where the nuisance was the greatest. (6) Assist the sanitary inspector of the park in locating water supplies for those automobile camps now without water except at long distances from the camps. (7) Accompany Acting Assistant Surgeon W. E. Crawbuck on all inspection trips to the hotels and camps, the latter to include Government camps of all kinds. All reports of inspections to be signed by both officers and to be submitted in duplicate to the superintendent of the park.

The work to be accomplished by Acting Assistant Surgeon W. E. Crawford in Yellowstone National Park during the summer is as follows: (1) Once in every two weeks, and oftener if necessary, visit all places in the park serving food or drinks to visitors or employees and make detailed report on sanitary conditions found. This work is to include kitchens, dining rooms, privies, toilets inside hotels and outside in the camps, handling of water in hotels and camps, and in general to note the sanitary condition of all places visited. (2) Visit the dairies or milk

dealers and make complete inspection of premises. This work is to include instruction in regard to cleanliness in handling milk, with special reference to properly sterilizing milk containers. The care and attention of the sick among the producers and dealers is to be emphasized. (3) Inspect the unloading stations at the entrances to the park to learn whether proper methods of handling perishable goods are observed. (4) Obtain all the data possible relating to the cause of diarrhea or dysentery in the park. One or the other of these disorders or diseases has been more or less prevalent in this park as well as in all the other national parks in previous years, and it is the intention to collect data from all the parks in regard to this matter.

Junior Assistant Sanitary Engineer Mars assisted the Oregon State Board of Health in investigating interstate carrier waters prior to making certain mosquito investigations in Mount Rainier National Park.

## Studies of Malnutrition of Baltimore Children

During the latter part of the last fiscal year, two hundred underweight children in Baltimore, all having one or more physical defects, were selected as a group for the study of the effect of the correction of physical defects on growth and development. Corrections included defective teeth, enlarged or diseased tonsils, adenoids, defects of hearing and vision, hernia, bronchitis, and phimosis.

Of these 200 cases, 153 children have had all reported defects corrected, 11 have had one or more corrections made, 17 refused correction and 19 left school before any corrections were made. To secure these results 255 visits were made to the two schools, 518 visits were made to homes, 410 visits to clinics and hospitals, 21 visits to welfare agencies and 6 visits to physicians.

The children in the group were weighed at frequent intervals. It was found that with only one exception every girl, after the correction of her physical defects, gained at a more rapid rate than the normal average.

Though the number of children studied is too small to make these results conclusive, they are highly suggestive. This investigation furnishes an important link in the evidence to the hampering effect of physical defects on growth and development and the benefits to be gained by their correction in childhood.

Agencies in 247 other cities

*A flexible shoe for your flexible foot*

Nature, in her wisdom, designed your foot arch to flex when you walk. Why restrain it in shoes that are rigid and without natural lines? "The foot is like a cantilever spring," wrote a noted doctor. "The Cantilever is the most comfortable shoe I have ever worn," said a trained nurse; and another woman said, "In Cantilever Shoes I feel as though I were flying."

It is because of the *flexible shank and natural lines* of the Cantilever Shoe that you will derive such comfort from it. And because of its graceful appearance and its harmony with this Spring's shoe styles you will see it worn wherever daytime costumes are worn. Fine workmanship, splendid materials and reasonable prices add to make the Cantilever desirable.

The graceful carriage and youthful walk of the Cantilever Woman are often admired. Her feet are free. She walks naturally, with a minimum of effort. Flexing with

every step, Cantilever Shoes make her feel as though she wore the wings of Mercury.

Though you may not be conscious of it, there are few things that spoil a good disposition quicker than shoes that nag you. Nerve strain, leading to backache, headache, and even to pains like those of rheumatism, may be caused by high heels and by shoes that bind and restrict the feet. Many writers on health and beauty subjects are now pointing out the importance of a woman's shoes in respect to her health, happiness, and personal attractiveness.

You were given two marvelously constructed feet. At the nearest Cantilever Store, try on a pair of shoes suited to their needs. Keep your feet well and spare yourself the misery that has come to so many women. If wrongly designed shoes have already begun to injure your feet, a change to Cantilevers will help them. Weakened arches will be strengthened by proper exercise; your improved circulation will make you feel better and look better.

If none of the listed dealers is near you, write the manufacturers, Morse & Burt Co., 1 Carlton Avenue, Brooklyn, N. Y., for a nearby dealer's address and for the Cantilever Booklet, which tells some things you will be glad to know about your feet.

**Cantilever Shoe**

## Juvenile Court Investigations

A COMMISSIONED medical officer for full-time duty and an acting assistant surgeon for the physical examination of females served with the juvenile court of the District of Columbia throughout the greater part of the fiscal year continuing the investigations begun in the early part of 1920. Complete physical and mental examinations, including the Wassermann tests, were made on each subject unless a part of such examination had already been made.

The results of these examinations were considered in connection with the family and personal history and court record in arriving at an understanding and classification of each individual examined. In each case a brief summary was made, with recommendations, for the use of the court and probation officers in the subsequent handling of the case. Practically all children appearing officially before the court were examined, an important point from a sociological standpoint.

The total number of children examined during the fiscal year was 684. Of the 49 white females examined mentally, 26 were normal, 3 mentally deficient, 3 retarded, and 17 showed constitutional psychopathic inferiority. There were 242 white males, the mental examination of whom showed 134 normal, 38 retarded, 23 mentally deficient, and 47 of constitutional psychopathic inferiority. Among the 300 colored males, 150 were normal, 90 retarded, 28 mentally deficient, 5 epileptic, 2 unclassified, and 25 showed constitutional psychopathic inferiority. Of 93 colored females, 62 were normal, 19 retarded, 6 mentally deficient, 2 epileptic, and 4 showed constitutional psychopathic inferiority.

The value that may result from medical work in connection with juvenile courts may be summed up as follows: (1) The detection and possible correction of physical defects at a period in life when they are most amenable to treatment. (2) The detection of mental defect, psychopathy, or other deviations from the normal at a period in life when corrective measures are of most value. For those subjects who do not profit by average training, adequate preparation can be made for special classes, manual training, or institutional control. (3) It affords medical examination and makes possible treatment for

a group of people who probably stand most in need of such aid. (4) A high type of medical work carried on in connection with juvenile court is probably of considerable value in the way of public health educational work in that each year for a large number

## Tuberculosis Association

THAT the health work carried on by the National Tuberculosis Association is instrumental in saving one hundred thousand lives a year was brought out by Hon. Charles E. Hughes, Secretary of State of the United States in his address before the Eighteenth Annual Meeting of the Association which met in Washington, D. C., May 4-6. Paying tribute to the achievements of the National Tuberculosis Association in checking a "terrible scourge of mankind," Secretary Hughes said that in no field of effort was there so much promise and opportunity as in that of conserving the public health.

After stating that he had been connected with the anti-tuberculosis movement in New York State since 1907, Mr. Hughes said: "According to the statistics, which apply to New York State outside of New York City, the death rate in this period has fallen from 129 to 86, a decrease of 34 per cent. That means, as I understand it, that last year in that part of New York State there were 2,700 fewer deaths than there would have been at the rate for 1907." In the District of Columbia, Mr. Hughes pointed out, the death rate among negroes from tuberculosis is less than half of what it was in 1880, and the death rate among whites is less than one-third.

On the general work of fighting tuberculosis Mr. Hughes said:

"It appears that since your Association was formed in 1905 the number of hospitals and sanatoria for tuberculosis have increased seven-fold and that the number of dispensaries has been multiplied by twenty-four, and that the number of public health nurses has risen to 10,000.

I understand that the death rate from tuberculosis in the registration area of the United States has decreased almost exactly one-half since this association began its work, which means 100,000 fewer deaths last year in the United States than there would have been had the earlier rate continued.

of children it is a practical illustration of what thorough medical examination and treatment consist of. (5) If capably performed it is of value to the court and probation officers in the proper understanding and handling of these children and at the same time increases the confidence of the probationers and their families in the efforts made in their behalf.

The collateral benefits of this movement are of the greatest importance. I do not speak simply of the obvious economic results. Rather I should emphasize the general attention to sanitation and the corresponding advance in conditions of well-being. To those who have labored in this movement, the nation is under lasting obligation.

In his annual report Dr. C. J. Hatfield, managing director of the Association, called attention to the fact that there were still about a million persons ill with active tuberculosis and that about one hundred thousand were dying annually from the disease.

Godias J. Drolet, statistician of the New York Tuberculosis Association, made an address, saying that tuberculosis killed almost twice as many men as women. He said the difference was due to the conditions under which they worked.

John A. Kingsbury, Secretary of the Milbank Fund, announced that a large part of the income from ten million dollars would be used in the next few years to demonstrate in New York State how tuberculosis could be controlled in communities.

Dr. Charles J. Hatfield resigned as managing director of the Association and Dr. Linsly R. Williams was appointed to succeed him. Dr. Hatfield will devote most of his time to local tuberculosis and health work. Dr. Williams was formerly Deputy Commissioner of health in the state of New York and for the last four years has served as director of the Rockefeller Commission on the Prevention of Tuberculosis in France. The following officers were appointed for the coming year: Dr. Lawrason Brown, president; Dr. Charles J. Hatfield and Dr. J. W. Pettit, vice-presidents; Dr. George M. Kober, secretary; and Mr. Henry B. Platt, treasurer.

The following directors were also elected: Dr. J. H. Peck, Iowa; Dr. David R. Lyman, Connecticut; Dr. W. L. Dunn, North Carolina; Dr. A. M. Forster, Colorado; Mr. John A. Kingsbury, New York; and Dr. James Alexander Miller, New York.

## Textbook of Nursing Procedures

A new "Textbook of Nursing Procedures," by Anna C. Jamme, R.N., is a series of demonstrations prepared to supplement the nursing manual and to place before the student of nursing the method of carrying out practical procedures before they are put into actual practice in the care of the patients. The material is simply presented and may be of convenience to the various schools of nursing. The equipment necessary for a demonstration room is tabulated, in addition to the articles required in each demonstration and the procedure to be followed, as, for example, the cleaning of utensils and sinks; the cleaning of the medicine closet. There are forty-one demonstrations enumerated, covering those in common use, given in the order of the course, the more complex and difficult problems being treated in the later lessons. The book is well illustrated and special points of difficulty are expanded and emphasized in the notes.

### Public Health Surveys

The sanitary or public health survey is a very important part of any attempt to improve local or general health situations. It is perhaps of the greatest use where there is a widespread ignorance of sanitation, but is also very effective in the better types of communities. Preventive measures must be based upon facts to be effective, and one of the principal objects of a sanitary survey is to reveal impending dangers and on the positive side, opportunities for new public benefits.

A recent book published by Murray P. Horwood on Public Health Surveys, what they are, how to make and how to use them is really a sort of textbook intended to serve as a guide to those who contemplate the making of public health surveys. An introduction by Professor George C. Whipple emphasizes the importance of various factors such as publicity, training, and reports, which, read in connection with the rest of the book, call attention to many possible pitfalls.

The book itself outlines methods to be used in making the survey, the sources of information to be found, the organization of the community for its survey, the character of the water supply; drainage, sewerage and sewage-disposal; the collection and disposal of refuse; the milk supply; the inspection of restaurants, lunch rooms and food stores; housing; school sanitation. Two chapters which should

perhaps be particularly emphasized deal with the preparation of the report and the methods of obtaining results from the survey.

A public health survey may be valuable in stimulating interest in conditions affecting health and health education; is almost the only means for obtaining any accurate picture of actual conditions; and finally is a powerful weapon for introducing health repairs. The Rockefeller Foundation made surveys primarily for its own information, while in Taunton and Quincy, Mass., surveys were made entirely for private information. Oklahoma, on the other hand, has thoroughly organized and conducted her surveys under popular auspices with the idea of following up the findings made. The public health survey can be a powerful instrument if properly wielded, but its best use depends on the thoroughness, accuracy, planning, and administration of the actual proposed work. The present book is not exhaustive but should be suggestive and useful to an interested audience. Quite a comprehensive bibliography is included which will enable further research to those so desiring.

John Wiley & Sons, Inc., New York, 1921.

### Alaska Needs Physicians

An attempt is being made by the United States Bureau of Education to do what it can to check the ravages of tuberculosis and other diseases among the native races of Alaska. For this work physicians and nurses of good educational qualifications, successful experience, upright character, and altruistic motives are desired. The field is one of great interest and of unlimited opportunity for the health worker.

A physician in the Alaska Medical Service is required to supervise one of the small hospitals maintained by the Bureau of Education or, under the Superintendent of Schools, to make tours of inspection of the schools in his district, furnishing medical relief to the inhabitants and endeavoring to maintain sanitary conditions in the homes and villages. The salaries paid to physicians in the Alaska Service range from \$1,800 to \$2,800, and those of nurses from \$800 to \$1,400 per year. The Bureau defrays traveling expenses. Persons desiring these positions are not required to pass an examination, but must make application on the form prescribed by the U. S. Bureau of Education.

## Devine's Social Work

SOCIAL work as a serious vocation and also as an avocation is attracting an increasingly large number of men and women desiring to devote their time and thought to the problems of poverty, ignorance, disease, and crime. Dr. Edward T. Devine, formerly of the New York School of Social Work, has recently published a book, one of a series, which seeks to explain the relationships and problems of the larger social movements of industry, education, and other related departments. There are few people who can speak with such intimate knowledge and authority as can Mr. Devine and his attempt at an objective and critical study from what he terms a detached point of view brings some very interesting thoughts.

The book itself is designed primarily as a text, the first part being devoted to the general development and scope of social work. The author has divided his study into four parts: the relief of poverty; the care of the sick, disabled, and defective; the treatment of criminals and the relief of living conditions. Various agencies and facilities for work are discussed, the methods of treatment, general

considerations relating to coordination and supervision, finance, and preparation for work.

The book is very evidently the result of years of thought and effort. Parts of it stand out as particularly keen analyses not only of institutional methods for meeting a given situation or problem but as a criticism of the entire theory of such institution. The problem of old age dependence is one to which generally we give too little attention. The almshouse is as Mr. Devine says "a very profitable introduction to social work."

There are in all studies or comments remarks or ideas to which exceptions can be made, differences raised, and points argued. We feel that the author is right in noting the transfer of attention as to the problems of social work from moral to physical defects or weakness. The problems here in large part center around the hospital, special dispensaries, or clinics. The shift here has brought about an increased public concern for the adequate treatment of the sick and a more intense demand for the elimination of these diseases which are preventable. The ideal of social work is to make it unnecessary.

## A new authoritative book on yeast

Written by a physician for physicians, this brochure discusses the manufacture, physiology, chemistry and therapy of yeast.

THE growing interest in yeast as a therapeutic agent has made it essential that physicians should have at their disposal some book of reference which will summarize in an authoritative way the present known facts about yeast.

This information, so necessary for the busy practitioner, has been ably brought together in a book entitled "The food value, therapeutic value, manufacture, physiology and chemistry of yeast, also a symposium on vitamins."

*The chapter headings speak for the variety to be found in this treatise. These headings are:*

What is yeast?  
The manufacture of yeast  
Yeast Therapy  
When and how to take yeast  
Care and properties of a yeast cake  
Boils, Furunculosis, Carbuncles, Acne  
Constipation  
General Debility  
Arthritis and Rheumatoid Conditions  
The vitamins  
Yeast vitamin B  
The vitamin C  
The vitamin A  
Fermentation and Enzymes  
The value of yeast as food

THE FLEISCHMANN COMPANY take great pleasure in announcing the publication of this book. They will be glad to send free of charge a copy of this book to

any physiological chemist, hospital or physician who will write to The Fleischmann Company, Dept. Y-5, 701 Washington St., New York, N. Y.

## The Child in the Foster Home

The New York School of Social Work has recently published a monograph, the second in a series of studies on child welfare, entitled "The Child in the Foster Home," by Sophie van S. Theis and Constance Goodrich. This monograph is a discussion of homes used by the New York State Charities Aid Association in its work of providing for dependent children in foster homes. It is an exposition not of ideal standards but of practical experience. The placing of dependent children in foster homes for adoption or for a more or less indefinite period necessitates: First, careful investigation of the child's family and personal history; second, an investigation of the foster family; third, supervision of the child after he is placed in a foster family.

In the first investigation, special stress is laid in the investigation of the family history upon feeble-mindedness, insanity, epilepsy, and venereal diseases. The social history including the conditions which necessitated permanent separation of the child from his own relatives, the child's background, the kind of care he has had, and the legal claim which the agency has upon him, are discussed in detail. Especial study is made of the child himself, his personality, habits, and health. A point is made of the mental and medical examinations.

The inquiry into the circumstances and character of the foster parents is discussed in detail with special emphasis on the necessity for checking all information given by the family by interviewing references, usually including the family physician.

A large part of the monograph deals with problems which may arise in the process of settling the child in his new environment. The supervision of the child's health, the use of clinics and occasional examinations by the staff doctor, is an important feature.

All phases of the work are amply illustrated by full case records quoted practically verbatim.

## Vocational Civics

A new book, entitled "Vocational Civics", brought out by Frederick Mayer Giles and Imogen Kean Giles as the report of a study of occupations as a background for the consideration of a life-career, is the best compilation of data we have seen by which to estimate the probable future in a given business or profession. Although we always felt the need of

a simple and comprehensible presentation of this subject, somehow vocational manuals and textbooks were not quite satisfactory. Almost invariably they have stressed the skilled mechanical trades, omitting professions and other life occupations. The authors, both of whom are competent instructors of long standing, treat this very important phase of education very broadly. The book itself is divided into thirteen chapters, outlining each profession or trade and approaching it from many angles. Each occupation is treated (a) from the qualification standpoint; (b) preparation; (c) opportunities and advantages; (d) disadvantages; thus giving the instructor and the learner a new way as to how to "find himself" and become a valuable member of the community.

The Macmillan Company, New York, 1922.

## Broader Training Urged For Dentists

Dean Smith of the Harvard Dental School recently declared as in favor of two years of college work as a prerequisite to admission in a first class dental school. The recent scientific development in dentistry and the problems still awaiting solution require that the same sort of advance which is taking place today in medicine shall be applied to dentistry. Sheer technical competence of the past must be supplemented by a training which takes into account the chemical relation between diet and teeth. The relation between the decay of teeth and rheumatism, neuralgia, heart diseases of various kinds, and many other ailments. The whole science of dentistry needs to be put on a firmer scientific foundation.

# Science in Social Work

IN "THE Scientific Spirit and Social Work," the author, Arthur James Todd, has attempted to show some of the problems of the social worker, the general trend of the social movement and social reforms. If a profession is to be established by the social worker she must objectify problems and activities to ascertain relative values and importance. Back of all true social work is the desire to serve but the "new quality which science adds to the impulse to serve is ordered intelligence and the discipline of knowledge." Social work may become a profession, if by that we mean that in addition to having an ideal of promoting social welfare, social workers will eventually become really qualified to do their work as no other profession can. "It will really become truly scientific only when every social worker sets as his ideal not drawing his meed of praise or money for turning off the day's work with as little friction as possible, but knowing the truth as it is and adding to the sum of truth for the creation of a world more worth living in and working for. To work for the truth that shall make you free—that is the scientific spirit."

Mr. Todd has very keenly analyzed the confusion of sentimentality and social reform, the part which the apostles of softness, the "sob squad" have played, bringing very just criticism and contumely on the heads of well meaning benevolents. Sentimentality, "the emotional ooze," in the field of child welfare for example

has killed a thousand times more babies than Herod did. Nearly anybody with a slight equipment of passing good looks and a bit of nerve can organize and foist upon the credulous public a charity for babies or children. "Save the Babies" will wring tears and dollars from thousands who would pass unheeded a call to "Prevent Infant Mortality." Social reform to be effective must be thought out and carried through with a scientific spirit utilizing every worthy quality of human nature but more and more retreating from the "driveling appeal to the froth in human nature." "When faith and love, vision and disciplined intelligence can be welded into one, we shall have such a corps of expert leadership that the very gates of hell shall not prevail against us."

Social problems arise first of all from faulty adaptation. These may be met in individuals by the case worker or by the group through legislative or preventive means. Mr. Todd has gathered some very profitable material on the dead center in social work, the problem of labor turnover, the haphazard methods of training and supervision and the problem of salaries and wages in social agencies. These have all received careful attention in industrial and financial circles and certainly should be considered more thoroughly in the field of social work. It might be well to straighten our own house before we seek other fields to conquer.

The Macmillan Company, New York, 1921.

# Sherman's Polyvalent Vaccines

**V**ACCINE therapy is based on two well-known factors:  
 (a) That antibodies develop, primarily, in the infected tissues during the course of an infection and when killed organisms are injected into healthy tissues antibodies are also formed by the tissues into which the killed organisms are injected thus exploiting inactive healthy tissues and forcing them to become actively engaged in antibody formation to aid the infected tissues in overcoming the infection, and, (b) That killed organisms when injected into healthy tissues are more dependable and safer agents towards stimulating tissue cells for antibody formation than the live organisms responsible for infective processes.

Sherman's Polyvalent Vaccines are dependable antigens for destroying or digesting the disease germs in

<b>Acne</b>	<b>Nephritis</b>
<b>Arthritis</b>	<b>Neuritis</b>
<b>Asthma</b>	<b>Otitis media</b>
<b>Bronchitis</b>	<b>Psoriasis</b>
<b>Erysipelas</b>	<b>Rheumatic fever</b>
<b>Gastritis</b>	<b>Scarlet-fever</b>
<b>Gonorrhea</b>	<b>Tonsillitis</b>
<b>Gonorrheal arthritis</b>	<b>Tuberculosis</b>
<b>Hay Fever</b>	<b>Typhoid fever</b>
<b>Mastoiditis</b>	<b>Whooping-cough</b>

Immunity to these bacterial diseases is aroused all along the line only by numerous different strains of selected vigorous type-true virulent organisms such as Sherman's Polyvalent Stock Vaccines contain.

Sherman's Vaccines are beyond the experimental stage.

 G. H. SHERMAN, M. D.  
 Detroit, Michigan**

## FROM THE FIELD

The Ohio Department of Health is conducting a correspondence course in public health for health commissioners. Dr. E. R. Hayhurst, Dr. F. G. Boudreau, and Mr. Paul Mason are on the committee in charge.

Fellowships in medicine to increase the supply of qualified teachers in medicine in clinical and laboratory subjects and in curative and preventive aspects have been announced by the National Research Council. The fellowships, supported by appropriations from the Rockefeller Foundation and the General Education Board, will be open to Americans or Canadians of both sexes holding or qualified to hold M.D. or Ph.D. degrees from approved universities. The appropriations total \$100,000 a year for five years. Successful candidates who are to be known as Fellows in Medicine of the National Research Council will be at liberty to choose the institutions or universities in which they will work.

Dr. Robert Olesen, epidemiological aide with the Wisconsin state board of health, made a preliminary survey of North Dakota's state health administration in March for the U. S. Public Health Service.

The Maternity Center Association, 432 Third Avenue, New York City, is conducting a scientific study of the essentials of complete maternity care including nursing service for women before, during, and after confinement in an effort to cut down the death rate of mothers and babies. Besides carrying on a house to house canvass and distributing pamphlets nationwide, the Center will also serve as a training center to prepare nurses to supervise the maternity work of general organization. Miss Mable Choate is president of the association.

In an effort to inform the citizens of New York how to preserve mental health, the Mental Hygiene Committee of the State Charities Aid Association has obtained the voluntary services of thirty-one noted psychiatrists and other authorities on mental hygiene for public addresses. Speakers will be made available upon application to Stanley P. Davies, Secretary of the committee, 105 East Twenty-second Street, New York City.

Not a single death or case of waterborne sickness has been traced to drinking water supplied by steam and electric railroads in Michigan the past two years, according to records kept by the State Department of Health. This degree of safety was reached, officials say, by rigid inspection of sources of water supply thus protecting the health of more than 25,000,000 passengers annually who, it is estimated, use the drinking water supplied by trains and interurbans. During 1921 a total of 304 samples of water from 135 sources used by 25 common carriers was analyzed. All except a few sources were found satisfactory.

The use of goat's milk as a food for infants and for the tuberculous as well as for ordinary usage is set forth by Joseph K. Calvin, S.B., M.D., in *The Archives of Pediatrics*.

S. Dana Hubbard, M.D., Director, Bureau of Public Health Education, is the author of Keep Well Leaflet No. 22 on "Social Hygiene" published by the Bureau of the Department of Health, New York City.

Claiming that physical training courses in the schools are not producing the results hoped for, Henry R. Allen of the Pennsylvania Bureau of Public Health Education, Department of Public Instruction, recommends that more time be given to physical education in the schools; that more adequate training be given not only to regular class teachers but to special instructors; that a standard course of study be prescribed; that greater facilities and equipment be provided; and that less time be devoted to interscholastic athletics and an effort be made to promote intramural sports.

The New York State Department of Health, through the courtesy of the General Electric Company, Albany, is broadcasting five minute health talks twice each week from the radio station at Schenectady.

The Twentieth Annual Conference of State and Territorial Health Authorities with the United States Public Health Service will be held at Washington, D. C., May 17 and 18, 1922.

A joint committee of the American Gynecological Society and the American Child Hygiene Association has outlined their work to include a complete scheme of maternal welfare with such departments as preservation of life and health of the mother; increase in the number of fruitful pregnancies; better facilities for the care of the unmarried mother; establishment of agencies of well qualified men to advise with governmental agencies.

A brief of many novel and unusual features has been filed in the United States Supreme Court by the Government in the child labor law cases. Solicitor General Beck quotes Shakespeare in support of the contention that the people must defend and preserve their own institutions. The brief also presents a historical paper on the French revolution with parallel column notations emphasizing the Government's case.

In attempting to lighten the economic burden of sickness, Dr. F. E. Harrington, Health Commissioner of Minneapolis, has shortened the usual period of quarantine for scarlet fever one week. This has resulted in no increase in the disease and has proved satisfactory from the medical point of view. Dr. Harrington states in the *New York Times*. Economically it has saved weeks of time to members of families. The Minneapolis department of health has also exploded the theory of fumigation after scarlet fever.

All projects in Peru for providing cities or towns with drinking water, sewage and drainage systems, and for garbage disposal must, according to a recent decree, be submitted for approval to the Public Health Bureau.

The First Medical Congress on Accidents to Workmen at Zaragoza, Spain, adopted the following resolutions: That hernia should entitle the victim to two months' wages or an operation at the expense of the employer; that the workman should be given the choice between a needed operation and the loss of his indemnity; that diseases contracted in the hospital as a complication of the accident or contagion entitle to compensation as does also death from the operation. Strict measures against malingering and vocational training for the disabled were also advocated.

# VIROL

*VIROL is a preparation of red bone marrow, marrow fat, malt extract, eggs, lemon syrup, and phosphates of lime and iron, in the form of an exceedingly fine emulsion, the fat globules being finer than those in human milk.*

## For Wasting and Delicate Children

**T**HE remarkable results obtained by the use of VIROL in Infant Feeding, for delicate children, and expectant and nursing mothers, is shown by the fact that more than 2,500 Hospitals, Infant Clinics, and Maternity Centers are regularly using this preparation.

The marked improvement in growth and development brought about by the administration of VIROL is due to:—

The presence of the vitamins in their active state.

The well-balanced nature of this food.

The ease with which it is assimilated in the most delicate conditions of the intestinal tract.

### BIO-CHEMICAL INVESTIGATIONS

In view of the extent to which VIROL is used in public health work in Great Britain, the Bio-Chemical Laboratory of the University of Cambridge recently conducted an exhaustive investigation to determine whether the vitamins known to be present in the raw materials from which VIROL was manufactured were present in their active state in the manufactured VIROL as sold to the public. The report, which fully proves the presence of the vitamins in VIROL, will be sent to any medical man on application.

*This very palatable nutrient is put up in glass jars: 50c, \$1.00 and \$2.00.*

*Sole Agents for United States*

**GEO. C. COOK & CO., Inc., 59 Bank Street, New York**

A "fitter family" contest conducted by the Division of Child Hygiene, Kansas Board of Health, is reported in the *Journal* of the Kansas Medical Society. Twenty-five families with an average of four to a family were completely scored. A silver cup was awarded by Governor Allen to the highest scoring family and medals were given by Senator Capper to all individuals scoring 90 per cent or above. Results showed that although the families scored above the average in education and intelligence, were in comfortable circumstances, and were so-called "well" people, they were badly nourished, showed need for better care of the feet, and for the avoidance of contagious diseases. The need for better obstetric and prenatal care was also found.

Eighty-eight per cent of the fresh meat used in the town of Paris, Texas, is slaughtered in the municipal abattoir says the *American City*. A veterinarian, bookkeeper, engineer, and three butchers are employed at the plant which maintains as part of its equipment an incinerator and curing plant. Raising hogs on the offal has been found profitable. The success of the plant is based on twelve years' experience.

The Medical Research Council of Great Britain has appointed a representative committee to advise upon the promotion of research into the biological action of light. This Committee will attempt to obtain better knowledge of the action of sunlight and other forms of light upon the human body in health or disease.

The Cincinnati Board of Health has completed a sanitary inspection of all barber shops in the city and rated them on the basis of 100 per cent. The ratings are published in the *Cincinnati Sanitary Bulletin*. Shop sanitation, sterilization, and individual service are the requirements stressed by the inspectors.

Dr. E. V. Brumbaugh, deputy health commissioner and chief of the bureau of child hygiene of the Milwaukee health department, has been elected full-time health officer of Madison, Wis. He has been with the Milwaukee health department since 1914, and has also been on the instructional staff of the Wisconsin Anti-Tuberculosis Association and the faculty of the Marquette University school of medicine.

Schedule 18, just issued by the United States Bureau of Mines, gives the procedure for establishing a list of permissible carbon monoxid indicators that are light in weight and portable for quickly and easily showing presence of carbon monoxid gas in mine rescue and recovery operations; or around blast furnaces, producer-gas and water-gas plants, and metallurgical and chemical plants. Examinations and tests of carbon monoxid indicators submitted by manufacturers will be made at the Experiment Station of the Bureau of Mines at Pittsburgh, Pa.

The Child Welfare Research Station of the University of Iowa has opened an experimental school for the normal child between the ages of two and four years. Physical measurements of the child are made once a month and investigations are made as to heredity, home conditions, and special characteristics of the families of the children as a background for the psychological findings. A new six room building equipped with child sized furniture has been opened. This is the first time that the reactions of normal children of this age have been studied. Dr. Bird T. Baldwin, director of the Station, is in charge of the study.

Ohio now has three women health commissioners out of a total of 169, according to the *Bulletin of the Ohio Public Health Association*. They are Dr. Beatrice T. Hagen, recently appointed commissioner of Zanesville; Dr. Inez Hyatt who on March 1 became health commissioner of Conneaut, succeeding Dr. W. H. Leet, and Miss Eleanor Loomis, Painesville, who has for some time been serving as both public health nurse and health commissioner of Painesville. Since the enfranchisement of women many women have been appointed on local boards of health and it is expected that more will be appointed as health commissioners.

American exhibits are desired in the British Food Exhibition to be held at London, September 6-26, 1922, at the Olympia, the largest permanent exposition building in England. Blank forms for application for space and information concerning the exhibition can be had from A. E. McKinnon, General Exposition Company, 405 Lexington Avenue, New York City, who is the American representative. Display of American fruits is especially desired.

Protection of water supplies from pollution and the public from preventable diseases, rather than saving of fish, is the purpose of the Michigan department of health in waging its campaign against stream and lake pollution and indiscriminate disposal of industrial wastes and domestic sewage. Private corporations are required by state law to file with the State Department of Health descriptions of the entire sewerage systems owned. Industries whose unsatisfactory disposal of wastes creates nuisances, kills fish, and pollutes water supplies are among the worst offenders. The Departments of Conservation and Agriculture will assist the State Department of Health in enforcing the stream pollution law.

All six of the laboratory workers of the U. S. Public Health Service who have been studying tularemia, a disabling sickness of man particularly prevalent in Utah, have contracted the disease, two of them being infected in the laboratory in Utah and the other four in the Hygienic Laboratory in Washington, according to an announcement by the Service. Such a record of morbidity among investigators of disease is unique in the history of experimental medicine. The disease is transmitted by the germ *bacterium tularense* which is transmitted by the bite of the blood sucking fly, the stable fly, the bedbug, and the squirrel flea.

In eleven counties in Ohio, the county and city governments have effected a combination of county and city health districts. Places where one commissioner serves both county and city are: Athens county and Athens City; Clark and Springfield; Erie and Sandusky; Greene and Xenia; Ross and Chillicothe; Shelby and Sidney; Summitt, Akron, Kenmore and Cuyahoga Falls; Wood and Bowling Green; Cuyahoga and Cleveland Heights; Clinton and Wilmington; Wooster and Wayne. Steps have already been taken to combine the city of Hamilton and Butler county exclusive of Middletown.

Benjamin S. Weiss of the University of Southern California has recently completed a study of 225 of the 1,500 children said to be annually employed in the production of motion pictures at Los Angeles. Teachers say that children so employed become excitable, precocious, unreasonably mature, and lacking in power of concentration.

# Stanolind Petrolatum

*A Highly Refined Product of  
Absolute Purity—Superior In  
Color To Any Other Petrolatum*

“Superla White” is pure, pearly white, all pigmentation being removed by thorough and repeated filtering. Does not contain nor require white wax to maintain its color.

“Ivory white,” not so white as Superla, but compares favorably with grades usually sold as white petrolatum.

“Onyx,” well suited as a base for white ointments, where absolute purity of color is not necessary. Compares favorably with commercial cream petrolatum.

“Topaz” (a clear topaz bronze) has no counterpart—lighter than amber—darker than cream.

“Amber” compares in color with the commercial grades sold as extra amber—somewhat lighter than the ordinary petrolatums put up under this grade name.

*Standard Oil Company of Indiana guarantees  
the purity of Stanolind Petrolatum in all grades*

**Standard Oil Company**  
(Indiana)

*Manufacturers of Medicinal Products from Petroleum*

910 S. Michigan Ave. Chicago, U. S. A.

Chicago has organized an Association for the Relief and Prevention of Heart Disease with Dr. James B. Herrick, president; Dr. Sidney Straus, secretary; Dr. Robert B. Preble, vice-president and Frank O. Hibbard, treasurer. The object of the association will be to coordinate the already established heart agencies, to direct those in need to the nearest clinic, to find agencies to provide for convalescent care, to cooperate with the Service League for the Handicapped in finding occupations suitable to their condition, and to carry on an educational campaign.

The American Society for the Control of Cancer has elected the following officers for the year 1922: Dr. Charles A. Powers, president; Dr. George E. Armstrong, Dr. Clement Cleveland, Dr. Livingston Farrand, Dr. Rudolph Matas, vice-presidents; Thomas M. Debevoise, secretary; Dr. Calvert Brewster, treasurer, U. S. Mortgage & Trust Co.; Sir Arthur Newsholme, honorary vice-president. Dr. Charles N. Dowd, Dr. John C. A. Gerster, Mr. Calvert Brewer and Mrs. Samuel Adams Clark, all of New York City, were elected to the Board of Directors.

The University of Cincinnati *Medical Bulletin* devotes its February issue to the Cincinnati Health Exposition held recently. The number contains the following articles: "The Cincinnati Health Exposition," by Bleecker Marquette, Cincinnati, Ohio; "National Ideals of Child Welfare," by Helen MacMurchie, M.D., Ottawa, Canada; "Fighting Typhus Fever in Poland," by Lient. Col. H. L. Gilchrist, U. S. A.; "What We Should Eat," by Harvey Wiley, M.D., Washington, D. C.; "Checking the Spread of Tuberculosis," by David Lyman, M.D., Wallingford, Conn.; "How Health Officials Guard the Public Against Disease and Death," by Royal S. Copeland, M. D., New York City; "Health and Dental Infections," by Weston A. Price, D.D.S., Cleveland, Ohio; "Rural Health Problems," by L. L. Lumsden, Surgeon, U. S. Public Health Service.

The Rockefeller Foundation has offered the sum of two million dollars towards the cost of building and equipping an Institute of Hygiene in London, the offer being made with the understanding that the British Government would provide for its staffing and maintenance.

Under the joint sponsorship of the Grinding Wheel Manufacturers Association of the United States and Canada and the International Association of Industrial Accident Boards and Commissions, there has been organized a sectional committee for formulating a safety code for abrasive wheels. The code prepared by this committee and approved by the sponsors has been approved as Tentative American Standard by the American Engineering Standards Committee. Copies of the code may be secured from the American Engineering Standards Committee, 29 West 39th Street, New York City.

The Annual Report of the State Division of Child Hygiene announces that the outstanding activity of the division for the year was the rural child health consultations for infants and children of preschool age conducted by a traveling field unit. The unit, which was composed of a physician, a nurse, and an advance agent, traveled by the "Healthmobile" during the part of the year when this was possible, visiting 108 rural towns, and examining over 5,000 children. During the winter, when roads were bad, 50 consultations were held in towns of 2,000 to 5,000 population easily accessible by railroad. No treatment was given but children with physical defects were referred to the family doctors. Follow-up work shows that at least 50 per cent of the cases so referred have received the needed attention.

The Information Bureau of the Division of Industrial Hygiene, Ontario Provincial Board of Health, offers to health officers, social welfare associations, industrial physicians, sanitary engineers, and employers means of keeping in touch with latest developments in industrial hygiene. Subjects covered are industrial medical service, industrial sanitation, occupational diseases, fatigue, and health legislation.

That there is a direct relation between infant mortality and housing is seen in a report by Dr. J. Parlane Kinloch in the *Lancet*. The mortality is not so great in relation to overcrowding of districts but to overcrowding of individual houses. The death in one-roomed houses in Aberdeen in 1920 were 25 per 1,000, in three-roomed houses 11 per 1,000; while infant mortality is twice as high in houses of three rooms and under as in houses of five rooms and upwards.

The Royal Sanitary Institute will hold a congress at Bournemouth, July 24 to 29, 1922, under the presidency of Major-General J. E. B. Seely, M.P. Conferences will be held on subjects relating to hygiene and sanitary science, and a health exhibit will be arranged in connection with the meeting.

Over thirty Maine organizations were present at a luncheon-conference held recently at Augusta to discuss the new health plan for Maine and the work of the Maine Public Health Association. Dr. Donald B. Armstrong, Executive Officer of the National Health Council, was the guest of honor.

The Cuban Society of Gastro-enterology was founded February 30 in Habana and officers elected March 13 as follows: President, Dr. F. Grande Rossi; vice-president, Dr. F. Torralbas; secretary, Dr. F. Solano Ramos; vice-secretary, Dr. Pedro Barillas.

The *Albany Medical Annals* recently published two articles relating to loss of vision, the first "Rating Losses of Industrial Vision under the New York State Compensation Law," by William Mehl, M.D., of Buffalo, and the second "Measuring the Loss of Industrial Vision," by A. N. Snell, M.D., of Rochester.

At the fourth annual convention of the Saskatchewan Society of Sanitary and Heating Engineers, at Regina, Saskatchewan, R. H. Murray, provincial director of sanitation, read a paper on "Sewage Disposal and Treatment."

The Third Pan-American Congress of Child Welfare will take place August 27 to September 5, 1922 at Rio de Janeiro in connection with the official program commemorating the centenary of Brazilian independence. The First Brazilian Child Welfare Convention will be held conjointly with those of the Pan-American Congress.

Health directors and members of eleven counties in Pennsylvania met at Pittsburgh recently under the presidency of Dr. Edward Martin, State Health Commissioner, and formed District Board of Health Association No. 4 composed of associated health boards. Drs. Israel B. Reed, Pittsburgh, and Albert J. Bearer, New Kensington, were elected vice presidents.

## Radiant Light and Heat for Infected Wounds

Discussing the usefulness of Radiant Light and Heat in his book "Medical Electricity and Roentgen Rays," Doctor Sinclair Tousey says:

*"They induce hyperemia and increase the number and activity of the phagocytes, and in this way they are valuable for local infections.*

*"Before suppuration they may hasten it if it is inevitable, and after suppuration they may hasten resolution.*

*"Infected, sloughing and sluggish wounds are successfully treated by ordinary incandescent light applied over a dressing wet with boric acid solution and covered with rubber cloth, and good results are obtained after laparotomy for appendical abscess, perforated gall-bladder; also in tuberculous and gonorrhoeal joint infections, carbuncles and furuncles, x-ray burns and frozen extremities."*

# Thermolite

## Light and Heat Applicator

A scientifically designed and well made applicator that reflects a flood of strong PENETRATING heat and light in PARALLEL rays—no focal spot to burn or blister.

Far superior to ordinary hot applications because the heat penetrates deep into tissues, is constant, always ready, acts quickly and is combined with beneficial light.

### USED IN ALL GOVERNMENT HOSPITALS

Try THERMOLITE in the Treatment of Neuritis, Rheumatism, Lumbago, Sprains, Stiff Neck, Burns, Ulcers, Carbuncles and Infected Wounds. Sold by electrical and surgical supply dealers. Write for interesting and instructive literature.

#### NO. 0670 OFFICE APPLICATOR

Reflector 12 in. diameter. Stand adjustable from 57 in. to 96 in. high. Consumes 375 watts at 120 volts A.C. or D.C. Covers area 300 square inches at 36 in. from reflector. Finish: Olive green and nickel. Price: Complete with stand, \$30.00.

#### NO. 0645 HAND APPLICATOR

Same design as 0670 only 8 in. diameter. Consumes 200 watts at 120 volts A.C. or D.C. Made of aluminum; weight 16 oz. Finish: Black and nickel. Price: Complete without stand, each \$10.00. Folding Stand for No. 0645, each \$6.00.

**H. G. McFADDIN & CO.**  
44 Warren St., New York

(Makers of Lighting Devices Since 1874)

## 4 MONTHS' RESULTS

A Springfield (Mass.) woman suffered from flat feet and bunions caused by wearing narrow-toed shoes. A local doctor advised her to wear

# GROUND GRIPPER

## WALKING SHOES

She did, and he kept careful diagrams of her feet from April 19th to July 10th. The above drawings are reproduced from his records. They speak for themselves.

"GROUND GRIPPERS" are the ORIGINAL muscle-developing health shoes for Men, Women and Children. They are universally recommended by physicians and surgeons. Instead of imprisoning arches and toes, they flex naturally with your feet in every part—at every step. Nerve pressure is relieved—stagnant circulation quickened—weak muscles strengthened—painful swellings reduced—deformed bones straightened. Feet are completely restored to normal shape, vigor and comfort. And these results are permanent.

"GROUND GRIPPERS" are imitated but never duplicated

Made only by

The *Lancet* publishes a common form of report for the medical examination of employees in a recent issue. Dr. D. A. Coles, Industrial Welfare Society, 51 Palace St., Westminster, S. W. I., drew up the report.

The Secretary of Commerce has recently approved an amendment to the general rules and regulations prescribed by the Board of Supervising Inspectors which requires that no candidate for original license as master, mate, pilot, or engineer shall be examined unless he has completed a course of instruction in "first aid" approved by the United States Public Health Service and has passed an oral examination based on a Manual on Ship Sanitation and First Aid recently prepared by the Public Health Service in cooperation with the Seamen's Church Institute of New York City.

The Massachusetts Institute of Technology offers a course in public health from July 10 to August 11 designed especially for teachers, school nurses, teachers of physical education, and those desiring to become laboratory technicians in the public health field. Courses offered are Methods of Teaching Hygiene and Public Health in the Public Schools by Prof. C. E. Turner; Personal Hygiene and Nutrition by Prof. John W. M. Bunker; Sanitary Science and Public Health by Prof. S. C. Prescott and Prof. C. E. Turner; Elementary Bacteriology by Prof. John W. M. Bunker and Dr. M. P. Horwood; Bacteriology (professional course) by Dr. Horwood; and Public Health Laboratory Methods by Dr. Francis H. Slack.

The Indiana Tuberculosis Association has issued a bulletin of advice "Get Well in Indiana," urging sufferers from tuberculosis not to go west where facilities for their care are inadequate, but to remain in their own state. Good food, rest, fresh air, and medical supervision are the essentials for tuberculosis cure and not climate, the report emphasizes.

Mayor James Couzens of Detroit has contributed personally to the new Children's Hospital one million dollars in securities. The Michigan State Hospital, to which the Mayor gave one million dollars in December, 1919, and the Children's Hospital have been consolidated.

Providence, (R. I.), school children are depositors in the Bank of Health which was founded by Dr. Charles F. Chapin, Superintendent Health Department; Dr. Ellen A. Stone, Superintendent Child Hygiene; Dr. Elliott Washburn, Providence Tuberculosis League; Mr. I. O. Winslow, Superintendent of Schools; Miss Ella L. Surrney, Assistant Superintendent of Schools, Primary Grades; and Miss Estelle C. Batchelder, fifth grade teacher, Broad Street School. The child marks each day on "deposit slips" the nine health rules he has followed and these in turn are recorded by the teacher on a blank, one for each child, and mailed at the end of the term to the Director of Physical Education, Geo. W. Watson.

A new department to be known as the Division on the Prevention of Delinquency has been created by the National Committee for Mental Hygiene, through its recent special gift from the Commonwealth Fund. One of the activities of the division will be to furnish, free or on a cost-sharing basis, psychiatric service to a limited number of juvenile courts throughout the country who may request it. A demonstration clinic staffed by a psychiatrist, a psychologist, and a psychiatric social worker will be assigned to each court to which it is possible to render such aid. The selection of courts will depend largely upon the interest shown and the prospects for the establishment of a permanent clinic at the expense of the community.

Another aspect of the work of this division will be to undertake inquiries covering a period of several years that will deal with the problem of delinquency in special population groups. The first study of this sort will be made in Monmouth, New Jersey, where an extraordinary opportunity presents itself to study the school children of a county. The work will be conducted in cooperation with a general program for child welfare, health, and education, and thus the practical work of treatment and prevention can be combined with medical and social research. Dr. V. V. Anderson, the director of the new division, will be in immediate charge of work and will be assisted by an advisory committee.

Wisconsin's tuberculosis death rate for 1921 was 73.8, the lowest ever attained in the state. For 1920 the rate was 84.6. The total tuberculosis deaths were 1,965, as compared with 2,217 for 1920.

France's new Minister of Hygiene, M. Paul Strauss, is by profession a journalist, and is well known in the public health press. He made his debut in politics in 1900 as a member of the Municipal Council of Paris. Later he was elected Senator from the Department of the Seine. He is President of the Association of Republican Journalists.

Massachusetts has a new organization, consisting of physicians called the Committee on Rural Health and Medical Service, which has inaugurated a plan to provide citizens of the State with medical care and attention similar to that which the hospitals, dispensaries, and specialists afford people in the cities. Hospitals will be established, subscribed to, and directed by the people and clinics will be conducted by specialists.

The British Chemical Society has published a report, "Notes on the Furnishing and Equipment of Chemical Laboratories," which relates the methods in use for forming and treating bench-tops, reagent shelves, fume cupboards, sinks, and waste channels, with notes on ventilation, supply services, and floor and wall surfaces added.

An epidemic of trachoma which has attacked 90 per cent of the population of Armenia is reported by Dr. R. T. Uhls of Kansas City who is head of the medical department of the Near East Relief. Of the 30,000 refugees examined, 27,000 were in the primary stages of the disease. Only an extensive medical campaign can save the country from becoming a nation of blind.

A neuropsychiatric clinic has been established by the department of public health at the Philadelphia General Hospital. The clinic will treat and observe patients who are not classed as insane and who have been discharged from the psychopathic wards of the hospital. It will also examine patients for early manifestations of mental diseases.

Scientific proof that typhoid patients are not carriers of the disease is provided by a new ruling of the Michigan Department of Health which requires that persons contracting typhoid shall be isolated "until specimens of feces taken at intervals of not less than one week after clinical recovery from the fever have been found free from the typhoid bacillus."

## The American Dollar and "AMERICAN" Sterilizers

An advertisement worth the reading of any interested in the purchase of sterilizing equipment—and directed particularly to those seeking the most for their expenditure.

**W**ITH all eyes centered upon Price, the purchasing power of the American dollar has never been so taxed as it is today.

We sense that you are not immune to the price appeal in the purchase of your equipment. You are seeking the very most your money will buy—and rightly so. It is, therefore, a source of keen satisfaction to us to know and be able to prove that

### Sterilizers and Disinfectors

at present prices represent the greatest Sterilizer and Disinfecter value obtainable. Notwithstanding the fact that they cost more to manufacture, due to the use of finer materials, more searching tests, more scientific and precise shop and machine work, more exacting inspection, and are consequently worth far more to the owner, they are sold today for less per unit of value than any similar apparatus made. Greater skill, greater specialization, greater achievement do not make the "AMERICAN" cost more—they do make it worth more.

And the purchase price, low as it is, is greatly lessened in the after years of uninterrupted service because of low maintenance and operating costs. Your dollar has been creditably spent when it goes for "AMERICAN" apparatus.

Descriptive bulletins, engineering data and specialists' counsel are free for the asking.

## MEDICAL AND HEALTH RECORD FORMS

**T**HERE is both a moral and a professional responsibility on all agencies engaged in organized medical and health service to maintain permanent records in such form that the results can be compared with the statistics of all other agencies in the same field.

*This calls for standardization of record forms.*

Because of unexcelled facilities for production, and because of our experience in the development in conjunction with the American College of Surgeons of standardized hospital record forms, the Faithorn Company is able to offer you a broad service in the development and the manufacture of medical and health record forms for all purposes.

If your present forms do not fully meet all requirements we shall be pleased to co-operate with you in solving your problems.

500 Sherman Street  
Chicago

## Industrial Rehabilitation in Pennsylvania

The recent "Report of Activities of the Bureau of Rehabilitation to January 1, 1921" of the Pennsylvania Department of Labor and Industry adds much light to our already convincing data on the rehabilitation of industrially disabled by the thoroughgoing report of activities of the Bureau of Rehabilitation in the Pennsylvania Department of Labor and Industry. "Rehabilitation," says the report, "in its final application, is an industrial conservation activity, human engineering, the adapting of disabled persons to proper tasks, tasks they can perform efficiently unhampered by their disabilities."

The Bureau was established in July, 1919, by special act of the Legislature and provided with an appropriation of \$100,000 to be devoted to administrative costs of the Bureau, to the purchase of artificial appliances, and maintenance cost not exceeding \$15.00 per week for the physically handicapped during a period of training. Such training courses include telegraphy, motor mechanics, traffic management, salesmanship, commercial courses, piano tuning, carpet weaving, watch making and other skilled occupations.

Of the 730 persons registered with the Bureau up to January 1, 1921, definite assistance had been extended to 310 disabled persons, 47 of whom were receiving regular weekly maintenance. Artificial appliances had been furnished to 166 persons. The records indicate that the majority of the registrants were over 31 years of age and native Pennsylvanians. The age factor is important in arriving at a decision regarding training. While the work has thus far been carried on as a state project, an agreement is under consideration with the Federal Board for Vocational Education and Federal funds will be accepted.

## Dietetics in Labrador

A study of the diet in Labrador is published in a recent issue of the *Journal of Home Economics*. The character of the food supply offers an excellent opportunity for observing the effects of simplified cereal and meat diet on a large group of people for a considerable period of time under fairly constant conditions. The observations covered the years 1919 and 1920 in order to determine the exact nature of the diet in the region and the incidence of diseases that were

supposed to be of nutritional origin.

Bread made of white flour is the chief article of diet. Whole wheat flour would be perhaps better in the restricted diet but the people do not like it and will only use it when ill. Salt meat, either pork or beef, is eaten in quantities. Game is the only fresh meat. Formerly it was plentiful but recently not so much so. Molasses commonly takes the place of sugar. The more prosperous families have occasionally potatoes and turnips and sometimes onions. Rice is not used generally. Dried peas are almost universal and are eaten once or twice a week. Some of the families have a small quantity of dried beans. Dock can be used as beans but are not usually eaten. Small quantities of canned fruit are occasionally provided but are not an essential part of the diet. Occasionally a family has figs or prunes. Cow's butter is exceptional and condensed and evaporated milk are both used, the sweetened condensed milk being the most popular. Tea is the universal beverage. Two to three cups are taken at every meal by young and old.

It is pointed out that the diet is chiefly that of cereals, with an excess of carbohydrate and a deficiency in vitamins and protein. The growth of children is retarded more markedly in the poorer families. Deficiency diseases are less common than would be expected.

## The Economic Aspect of the Sandwich

Physicians generally have not been primarily interested in the sandwich as an important part of the diet but its universal use has led to an effort to estimate the caloric content of the ubiquitous sandwich. The nature of

the health problem involved in the use of the sandwich depends upon the place it occupies in the dietary. Eaten with a cup of tea as a noonday meal, a sandwich of high energy content constitutes no health problem. If taken between meals however in addition to an adequate ration, it may become an individual health problem. Its economic aspect becomes important when the sandwich of inadequate calories is depended upon for food.

Generally speaking, aside from sliced chicken sandwiches, the higher the price of the sandwich, the larger the number of calories. A frankfur sandwich at five cents is an economical source of energy, but a sliced bacon sandwich at twenty-five cents must be considered as a concession to the demands of the palate and not as an economic source of energy.

A report of the ready-prepared sandwich has recently been made by Cornelia Golay Benedict and F. G. Benedict, of Boston, and their report from the nutrition laboratory of the Carnegie Institute in Washington is reported in a recent issue of the *Boston Medical and Surgical Journal*. The main object of their inquiry was to determine the total calories in the various types of sandwiches. Roughly speaking, they found the number of calories not far proportional to the total weight of the sandwich. The estimation of the energy content of the salad sandwiches is a more complex matter.

The chief food value is in the bread. Disregarding the cost of labor and the convenient but often elusive "overhead" charge the purchaser paid at the rate of about \$7.70 per pound for the chicken meat in the sandwiches tested in this study. In general, it is concluded that the sandwich is not an economical source of energy.

## Rest for Detroit School Children

Courtesy of City Health.

Rest following luncheon is one of the prescribed rules for pupils in Detroit's open air school who are below par physically.

# LOESER'S INTRAVENOUS SOLUTIONS

## Every Physician Should Read THE JOURNAL OF INTRAVENOUS THERAPY

A sixty-four page Journal, containing original articles, reprints and abstracts relative to Intravenous Medication from foreign and domestic medical journals.

The most comprehensive compilation on the subject, including laboratory and clinical reports.

Copy mailed on request.

### NEW YORK INTRAVENOUS LABORATORY

100 West 21st Street

NEW YORK, N. Y.

*Producing Ethical Intravenous Solutions  
for the Medical Profession Exclusively.*

# Arhovin

No matter what your favorite local treatment in Gonorrhoea and its complications, you can render it more *promptly* and more *permanently* effective by supporting it with internal Arhovin medication.

For over fifteen years, Arhovin has successfully taken the place of santal oil and balsams in the practice of a host of specialists and general practitioners, because it does not irritate the stomach, or kidneys, nor impart a tell-tale odor to the breath.

Furnished in tins of fifty capsules, each 4 minims.

Dosage: One or two capsules, three to six times daily, after meals.

## Mouth Hygiene for Dental Hygienists

The second edition of "Mouth Hygiene" compiled and edited by Alfred C. Fones, D.D.S., is an excellent outline of the subjects needed by a dental hygienist. Chapters are contributed on the various subjects of anatomy of the head, by Robert H. W. Strang, M.D., D.D.S., histology of the teeth and associated structures, by Dr. Strang; the teeth as a masticating machine, by Charles R. Turner, M.D., D.D.S.; malocclusion of the teeth, by Rodrigues Ottolengui, M.D.S., D.D.S., LL.D.; inflammation, by Leroy M. S. Miner, M.D., D.M.D.; deposits and accretions upon the teeth, by Edward C. Kirk, D.D.S., Sc.D., LL.D.; pyorrhea alveolaris, by Arthur H. Merritt, D. D.S.; dental caries, by Dr. Kirk; odontalgia and neuralgia, by Arthur Hopewell-Smith, Sc.D., L.R.C.P., M.R. C.S., L.D.S.; relation of oral infections to general health, by Dr. Kurt H. Thoma, D.M.D.; dental prophylaxis, by Dr. Fones.

Under dental prophylaxis, Dr. Fones treats in detail the subjects of instrumentation and polishing. The most efficient kind of toothbrush and the best means of brushing the teeth are described.

The appendix describes briefly the broad field of the dental hygienist in private practice, hospitals and sanatoriums, industrial and municipal clinics, and in schools. Dr. Fones' report of five years of mouth hygiene in the public schools of Bridgeport, Conn., is also published as part of the appendix.

The book is clearly and simply written and is well illustrated with plates.

Lea & Febiger, Philadelphia, 1921.

## The Story of Mankind

What H. G. Wells has done for adults in his "Outline of History," Hendrik Van Loon has accomplished for children in "The Story of Mankind." Most histories for children presuppose the establishment of the supremacy of man. Formal Ancient Histories may touch briefly on the "Stone Age," "Iron Age," and the "Age of Bronze" but Van Loon begins at the beginning. In a clear way easily understood by the immature mind, the author sketches the development of life from the first moving cell in dark waters to invertebrates, amphibians, reptiles, birds, mammals, till man, representing the highest type of animal life, is reached.

One is impressed with the fact that

the author is attempting to give to the child a synthesized knowledge of world civilization; the contribution of each age or people is stressed rather than events or dates. The book is not a thesis, as so many child's histories are, to uphold the superiority of Christianity; all religions and philosophies are accorded unbiased mention. The child reading "The Story of Mankind" will lay a basis for broadminded tolerance; will see history as a record of human achievement; will understand the influence of one country's civilization on the other, and will attain at an early age some concept of the international viewpoint.

The book is delightfully illustrated with naive outline drawings by the author.

Boni and Liveright, New York, 1921.

## Books Received

**AMERICAN APPRENTICESHIP AND INDUSTRIAL EDUCATION.** By Paul H. Douglas, Ph.D. Studies in History, Economics and Public Law, edited by the faculty of political science of Columbia University. Longmans, Green & Co., New York, 1921.

**ABDOMINAL PAIN.** By Prof. Dr. Norbert Ortner, chief of the second medical clinic at the University of Vienna, pp. 362; cloth, Svo. Rebman Company, New York, 1922.

**THE GLANDS REGULATING PERSONALITY.** By Louis Berman, M.D., Associate in Biological Chemistry, Columbia University, cloth, Svo., pp. 291. The Macmillan Company, New York, 1922.

# A Master Magazine

SIX THOUSAND people located in all parts of the world subscribe for the issues of *The MODERN HOSPITAL*—six thousand people realize the intrinsic value of each copy. The clinics, hospitals, institutions, and interested hospital workers are finding valuable editorial matter and interesting illustrations in every issue.

You may not be officially connected with or directly interested in a hospital, but prominently evident in all public health and social service organizations is and always will be the influence of the hospital. In this era of rapid development, you will want to keep in touch with the newer ideas as they are presented in each issue of *The MODERN HOSPITAL*.

Start your subscription now. Have a copy of the magazine sent to you personally each month. The yearly subscription rate is \$3.00.

THE MODERN HOSPITAL PUBLISHING CO.  
22 East Ontario Street, CHICAGO

The Dermatological Research Laboratories were first in the United States to produce Arsphenamine.—Due to the systematic efforts of our research staff, with laboratory facilities and personnel adapted to intensive concentration largely in this particular field, we are now producing a

## NEO ARSPHENAMINE

of such low toxicity and high therapeutic effect that it may be regarded as a super neo arsphenamine.

For the convenience of physicians who have not ready access to reliably distilled sterile water, we supply a bulk package (illustrated) containing 10 ampoules of any one dosage of neo arsphenamine with 10 ampoules of chemically pure sterile water (free from organic matter.) Solution may be effected in the ampoule and syringe.

## A Dignified Service

Few periodicals of any type have developed a classified advertising standing equal to that of THE MODERN HOSPITAL.

It is a unique achievement. Hospitals and people in the hospital field have, by their repeated use of our columns, broken down the impression that want ads are undignified.

Have you tried a classified advertisement in THE MODERN HOSPITAL to help you dispose of some used article? It has served many superintendents very successfully in this way.

Let the classified advertising columns of THE MODERN HOSPITAL be of service to you.

## Purification of Drinking Water

There is a constantly growing interest in the question of purification of water supplies used for drinking and also the purification of swimming pools, which is probably an outgrowth of Army necessities during the recent war. The *Bulletin de l'Academie de Medicine*, says:

Dopter and Rieux refer to the satisfactory results obtained in the French Army in the chemical sterilization of drinking water. The potassium permanganate and iodine tablet methods were soon abandoned in favor of the simpler and much cheaper sodium hypochlorite or "javelization" procedure. The chief difficulty in applying the latter was to secure an automatic apparatus which would bring the hypochlorite in contact with the water as fast as the latter was used and cease adding it when the outlet was closed. By 1917 several successful forms of apparatus for this purpose had been devised, and these the author describes. Bacteriological studies showed that colon bacilli disappeared completely from water thus treated, and that the mechanical mixing of the water reduced by one-half the amount of hypochlorite required. The water had no residual taste, and the users remained entirely unaware that it had been chemically treated. The only district in which complete success was not obtained was in the Argonne, the water there being rich in clay and fixing a considerable proportion of the chlorine. The method as a whole proved a potent factor, in conjunction with antityphoid vaccination, in eliminating water-borne diseases from the war zone. It seems to have solved the problem of water purification for armies engaged in stationary warfare, though apparently impracticable for troops in active motion. Apart from war conditions, the method would seem to be of great value not only in colonial hygiene but in affording a reliable means of securing good water in towns and villages where the costly procedure of purification applicable to large cities are impracticable.

## Encephalitis a World Wide Disease

Statements of delegates before the Session Extraordinaire d'Avril 1920 du Comité Permanent de l'Office international d'Hygiène Publique, Paris, 1920, formed the basis of a statement in a recent issue of *Public Health Reports* in regard to the world wide prevalence of encephalitis lethargica. The disease was announced in Austria by von Economo at the beginning of 1917, it reached France and England in the spring of 1918, and Italy the following winter. It appeared in Portugal in February 1919, in India in November, and in Spain in the early part of 1920. It appeared in the United States toward the end of 1918, on the

Atlantic Coast, and on the Pacific Coast in October, 1919. It also reached Uruguay, South America, and was present in Australia in March, 1919. It is a notifiable disease in England and Wales, from which countries it is reported as seasonal, being more prevalent in winter and mostly affecting individuals under 35 years of age.

It is not placed in the category of notifiable diseases in France but in that country systematic inquiry has been directed toward (1) communicability of the disease; (2) its relation to influenza; (3) its relation to poliomyelitis. It has not been reported in epidemic form in France, nor has communication by direct contact been established there. Children and adults are attacked in the ratio of one to two, deaths occurring in the same ratio.

The disease has been the subject of laboratory research in Italy where its occurrence has been sporadic, and comparative immunity has been noted in maritime climates. Notification is obligatory in Christiania and Poland.

The disease is not reportable in most of the countries and in but few cities and states of the United States, and the figures here given are, in most instances at least, fragmentary and a bare minimum. Reporting is obligatory in England and Wales, Christiania, Norway, Poland, and Zurich, Switzerland.

## Education Through Nutrition Classes

Educational work in nutrition classes is being developed in Schuylkill County, Pennsylvania, under the direction of the Home Economist, Elinor R. Mills, of the Anti-Tuberculosis Society. School children are weighed and measured and given tags

showing their underweight. On the reverse side of these tags are simple suggestions for bringing their weight up to normal. This weighing is followed by the establishment of special classes for the children who are more than 10 to 15 per cent underweight. Twelve classes have already been formed in various schools of the County, most of them being held in the school buildings during school hours. The 285 boys and girls in these classes are being taught practical things to do to gain in weight. Special emphasis is made on health-ation of oatmeal, baked potato, spinach, milk toast and other good foods for children is demonstrated each week. The children taste the foods prepared, and are urged to use them at home. A bulletin containing the information given in the class talk and demonstration is sent home with the child.

The gain which each child makes is pictured on an individual chart. Colored circles are also marked on these charts if they take a daily nap, go to bed early, drink no coffee, eat oatmeal, and drink three glasses of milk each day during the previous week. If a child fails to gain normally a doctor's examination is secured. The nutrition worker does some home visiting and is also securing the cooperation of community nurses and interested mothers in helping carry the work into the homes. The gains in weight and the children's improved physical conditions are already proving the practical value of this type of county class work.

The Bureau of Child Welfare of the Wisconsin State Board of Health has placed a child welfare motor truck in the field for service in distinctly rural counties.

## Detroit's Nutrition Class

Courtesy of City Health.

Children suffering from malnutrition in the Detroit public schools are segregated in a special class for medical supervision where an effort is made to bring them up to normal weight and health.

#### STATEMENT OF THE OWNERSHIP, MANAGEMENT, CIRCULATION, ETC., REQUIRED BY THE ACT OF CONGRESS OF AUGUST 24, 1912.

Of THE NATION'S HEALTH, published monthly at Chicago, Illinois, for April, 1922.

State of Illinois, )  
County of Cook ) ss.

Before me, a Notary Public, in and for the State and county aforesaid, personally appeared Dr. O. F. Ball, who, having been duly sworn according to law, deposes and says that he is the president of The Modern Hospital Publishing Co., Inc., and that the following is, to the best of his knowledge and belief, a true statement of the ownership, management (and if a daily paper, the circulation), etc., of the aforesaid publication for the date shown in the above caption, required by the Act of August 24, 1912, embodied in section 443, Postal Laws and Regulations, printed on the reverse of this form, to wit:

1. That the names and addresses of the publisher, editor, managing editor, and business managers are:

Publisher: The Modern Hospital Publishing Co., Inc., Chicago, Illinois.

Editor: Board of Editors.

Managing Editor: John A. Lapp.

Business Manager: James G. Jarrett.

2. That the owners are: (Give names and addresses of individual owners, or, if a corporation, give its name and the names and addresses of stockholders owning or holding 1 per cent or more of the total amount of stock.)

The Modern Hospital Publishing Co., Inc., Chicago, Ill.; Dr. Otho F. Ball, Chicago, Ill.; F. M. Bailey, Chicago, Ill.; James G. Jarrett, Chicago, Ill.; Alfred P. Sloan, New York, N. Y.; A. F. Nagle, New York, N. Y.; James Moores Ball, St. Louis, Missouri; Naomi E. Ball, St. Louis, Missouri.

3. That the known bondholders, mortgagees, and other security holders owning or holding 1 per cent or more of total amount of bonds, mortgages, or other securities, are: (If there are none, so state.) There are no bondholders, mortgagees, or other security holders.

O. F. BALL, President.

Sworn to and subscribed before me this twentieth day of March, 1922.

[Seal]

J. P. McDERMOTT, Notary Public.

My commission expires August 9, 1925.

## Rebuilding The Man

You are frequently consulted by men who have shot their physical and mental bolt.

You prescribe and lay out a well-arranged course of treatment—in fact do everything that scientific skill can do. In most cases the difficulty is that the patient, though his intentions are excellent, is unable to maintain the regimen laid out for him.

You may recommend a change and rest. The watering places, with their gay social life and travel, with its attendant burdens, do not bring rest, which is what the system craves and what you desire he shall secure.

A change to be most beneficial, must be complete—not only change of scene, change of habits, thoughts, diet, occupation, but in short a radically different mental and physical environment.

## Brown's Physical Training Farm

With its perfect equipment and ideal surroundings, affords just the change.

A 300-acre farm upon the bluffs opposite and overlooking West Point assures a high elevation with a restful scenic view.

Fresh vegetables, fruits, and other produce from the farm, and milk from a herd of registered tuberculin-tested Jersey cattle, bountifully supply the table.

A well-equipped Gymnasium, with steam baths, tennis courts, hand ball courts, horse back riding and swimming, are all a part of the regimen at this farm in bringing your patient back to normal.

A Manor House, especially constructed, offers accommodations in individual rooms. The training and physical upbuilding is under my personal supervision, and I solicit correspondence with physicians having cases requiring rejuvenation.

Send for booklet, *Rebuilding the Man*, containing detailed information as to cost, and reference from leading physicians as to my work.

**William J. Brown, Physical Director**

## Conference of State and Territorial Health Authorities

The following program is tentatively announced for the Twentieth Annual Conference of State and Territorial Health Authorities with the United States Public Health Service to be held at Washington, D. C., May 17 and 18, 1922.

Opening remarks by the Surgeon General.  
Roll call of delegates.  
Appointment of committees.

### REPORT OF STANDING COMMITTEE

Morbidity Returns—Dr. Eugene R. Kelley.  
Sanitation of Public Conveyances—Dr. Oscar Dowling.  
Interstate Quarantine Regulations—Dr. John S. Fulton.  
Rural Health Work—Dr. W. S. Rankin.  
Trachoma—Dr. John McMullen.

### SPECIAL REPORT

Progress report of Board appointed by the Surgeon General to study the problem of sanitary disposal of human excreta in unsewered communities—Professor C. W. Stiles.

### NEW BUSINESS

Anthrax.  
Discussion of Amendments to Interstate Quarantine Regulations.  
Problems of Interstate Health Work—  
Control of water supplies used in interstate traffic: (1) Discussion of chlorin as a means of insuring the safety of drinking water. (2) The value of colon bacillus as an index of potability of water. (3) Cooperative certification procedure.  
Coordination of effort and promotion of efficiency in the field of sanitary engineering.  
Transportation of lepers. Uniform parole system.  
Trachoma.  
Cooperative malaria control work: (1) Paris green as a larvicide. (2) Methods of evaluation of results of local measures for the control of malaria.  
Registration area for morbidity.

The relation of the public and the medical profession in the conservation of health.

Veneral diseases: (1) Proposed program for the ensuing fiscal year. (2) State work in venereal disease control.

Cooperative rural health work.

Child hygiene: (1) Resume of activities of the Public Health Service. (2) Provisions of the Act of November 23, 1921, entitled "Promotion of the Welfare and Hygiene of Maternity and Infancy, and for other purposes," with special reference to detailed plans for carrying out the provisions of the act as specified in Section 8. (3) Effect of distribution by official agencies of biologic products on child morbidity and mortality.

Toxin-antitoxin and the Schick reaction: (1) Statewide programs for the application of the Schick test and toxin-antitoxin immunization. (2) Standardizing technique.

Sanitary supervision of milk supplies.

Nutritional diseases.

Vaccination against smallpox.

Industrial hygiene.

Report of the conference on the education of sanitarians.

Immigration problems.

Rabies eradication by vaccination of dogs.

## Pennsylvania Conference of Industrial Physicians

The following program is announced for the Fifteenth Conference of the Industrial Physicians and Surgeons of Pennsylvania to be held at Harrisburg May 25, 1922, under the chairmanship of Dr. Francis D. Patterson, chief, Division of Industrial Hygiene and Engineering, Pennsylvania Department of Labor and Industry.

### MORNING SESSION 9:30 A. M.

Factors in Determining the Length of the Work Day, by Reynold A. Spaeth, Ph. D., associate in physiology, School of Hygiene and Public Health, Johns Hopkins University, Baltimore, Md.

The Problem of the Mental Misfit in Industry, by George K. Pratt, M.D., Medical Director, Massachusetts Society for Mental Hygiene, Boston, Mass.

Physiological Effects of High Temperatures and Humidities, by W. J. McConnell, M.D., past assistant surgeon, United States Public Health Service, detailed to United States Bureau of Mines, Pittsburgh, Pa.

### AFTERNOON SESSION 2 P. M.

Adequate Artificial Illumination as a Means of Improved Production and Protection to the Industrial Worker (illustrated), by G. Bertram Regar, illuminating engineer, Philadelphia Electric Company, Philadelphia, Pa.

How Best to Meet the Problem of Septic Infection in Industry, by A. W. Coleord, M.D., plant surgeon, Carnegie Steel Company, Clairton, Pa.

General discussion.

### EVENING SESSION 8 P. M.

Joint Session with the Association of Governmental Labor Officials of the United States and Canada.

The Industrial Clinic for the Rehabilitation of the Injured of Industry (illustrated by lantern slides and motion pictures), by General Lewis T. Bryant, commissioner of labor of New Jersey, Trenton, N. J.  
Medicine and Industry, by John A. Lapp, Chicago, Ill.

The activities of the Hospital Social Service Department in the University Hospital, Ann Arbor, Mich., receive new impetus and an earnest of future accomplishment in the appointment of Miss Dorothy Ketcham as director. Miss Ketcham was for some years identified with social service work in the University of Indiana. She served with the Red Cross during the war, since which time she has acted in the capacity of research assistant to John A. Lapp. She carries to her new post an unusual equipment for broad and effective work.

## Doctors Need Protection

Just as much as business men. In some ways they need it more.

A Doctor's business cannot very well be carried on by his family; yet it means the same to them as the business of a merchant or banker.

The Doctor's stock in trade depends upon his professional training, skill and ability.

Every professional man is in duty bound to give some consideration to the conditions which affect his business, his family and his old age.

# Nebraska Hot Lunch Clubs

BY MARY-ELLEN BROWN, ASSISTANT CLUB LEADER, LINCOLN, NEBR.

A RURAL teacher, who has thirty pupils in her school, said the other day, "I have served hot lunches in my school for seven years. This winter we tried the Standard Club plan for the first time and have found it to be a splendid method. In less than a week I realized that the boys and girls were taking much of the responsibility off my hands. I never want to go back to an unorganized plan of handling the work again."

The Nebraska plan involves organization of the school as a club with the boys and girls over ten years of age as active members. The active members are divided into groups. In order to divide the work, two work together, depending upon the size of the school. Each group serves a week as housekeepers, a week as cooks, and then as bookkeepers. Some time later they serve again for three weeks. By dividing the work in this way, only a comparatively short time is taken by the pupil from his work or play.

To increase the interest in doing the work quickly, each member keeps track of the number of minutes that it takes to complete the task. Each is asked to "beat his own record." For example, if it took fifteen minutes to wash the dishes the first day, the next day it should take only fourteen minutes. Such a check on time adds to the interest and the spirit in which the work is done.

Only one hot dish a day is prepared and the pupils bring the food from home. They take turns in doing this and each is given credit for the food which is furnished. A system of single entry bookkeeping is kept by the bookkeepers. As one boy said "bookkeeping makes the work so much

more interesting and worth while:

Miss Maude A. Bean, County Club Agent in Dawson County, in her monthly report, says "The teachers say it is wonderful the subjects one can correlate with the hot lunch club plan. We find that some teachers are making a great effort to develop sanitation, health and nutrition in hot lunch lessons. Another says her pupils are more courteous since having the club. Wherever a local leader is making special effort to carry out the club plan she is obtaining results."

James Ross has found that a man can handle hot lunches successfully through the club plan. In a letter Lela Robinson, a member of his club, wrote to the other boys and girls of her county, she says: "At first we get a Charter, signed by the Secretary of Agriculture Henry C. Wallace, and the Governor, Samuel R. McKelvie.

"There are three parts to the club work, cooking, housekeeping, and bookkeeping. Now I will tell you about the cooking. The lessons are very simple, so that even a small child could follow them if they could read. Housekeeping is simple, too. They are supposed to see that supplies are brought, serve, and wash the dishes. Each one in the club brings supplies when he is called upon. The bookkeeping is a little hard the first week but after that it is easy. We have cooked all kinds of lunches, some of them were cocoa, baked apples, potato soups, and creamed soups. We had a judgment contest at one of our meetings and made butterscotch candy. We are going to serve our mothers and fathers a lunch Friday. We have had good lunches so far."

## Generalized Plan of Public Health Nursing

The danger of over-specialization of the public health nurse and the consequent loss of centralized supervision is discussed by Allen W. Freeman, M.D., of Baltimore in an article entitled "Organization of Public Health Nursing in the State Board of Health," in *The Public Health Nurse*.

A public health nurse is often called upon to perform duties in connection with several diseases in one family or one district. Over-specialization in tuberculosis, communicable diseases, or child hygiene may work to the exclusion of interest in other lines, and thus involve a loss in time and efficiency. One public health nurse operating in a district can secure the confidence of the people more readily than several specialized nurses.

The generalized plan of public health nursing has been adopted to offset the weakness and decentralization of the over-specialized type. In this plan the nurses work by districts not by special problems or diseases, and each is assigned to a district for which she is responsible. To administrate this work properly there must be a division of public health nursing at the head of which is an experienced public health nurse to whom the other nurses are responsible.

Care should be taken not to confuse the work of the division of public health nursing with the division of child hygiene.

The division of public health nursing in a state department of health should act as consultant and adviser to all local voluntary and official agencies carrying on local nursing service. This should include assistance in securing suitable nurses, in establishing standards of work, and in formulating general policies and plans.

## SATISFIED AND SATISFYING

THE varying nature of industrial work demands certain qualities on the part of the industrial surgeon. Some industrial surgeons will meet the requirements in one industry and would perhaps be at "sea" in another plant. If an industrial surgeon is not satisfied with his work, or if he does not produce the results that should follow, the relation between the plant and the surgeon are certain to be unsatisfactory.

Aznoe offers a particular service for both industrial surgeon desiring plant connections and industries needing surgeons. The satisfaction that results when Aznoe's service is employed is due primarily to the care and intelligence employed in selecting the surgeon that will fit a particular need and will be satisfied with the plant conditions. Aznoe is not an employment agency, but rather a placing service that recognizes the needs of both individual and firm.

*Let us send you full particulars regarding this special service. The same careful placing service is likewise applied to industrial nursing.*

## Measures of Health Protection on Public Carriers

### Sanitary Regulations of Canadian Pacific Are Safeguard to Traveler

BY EMMA GATES ARMSTRONG, NEW YORK CITY

SEMI-ANNUAL house cleanings have long been the bugbear of housewives, but the up-to-date hotels of today are undergoing a perpetual house-cleaning, while passenger boats and cars are thoroughly renovated after each trip. The efforts made by public utilities companies to protect the health of the patrons they house or transport are unceasing. This may be illustrated by studying the method of the Canadian Pacific Railway Company. Its hotels, famous for excellence of cuisine and service, are strung along its transcontinental line from the Atlantic to the Pacific Coast and its great fleet sails the seven seas, the Great Lakes, and southern British Columbian lakes.

Passenger car cleaning is under the supervision of the mechanical engineering department, and all rules and regulations for this, as well as other departments, originate at headquarters at Windsor Station in Montreal. In order that there may be no misconception or excuse for infringements of rules, bulletins setting forth in clear, concise form the methods of cleaning and operating cars are put in the hands of the employees who are responsible for the cleansing of cars in the yards and of their care during runs.

Not only is rigid cleanliness demanded and attempted, but preventive sanitation is applied wherever feasible. The community towel and cup have disappeared and in their place

*That public utilities companies realize the need for cleanliness and sanitation and as a matter of routine protect the health of their patrons is shown by the safeguards with which the Canadian Pacific Railway Company surrounds travelers on its lines.*

*Cars are renovated after each trip; bedding on Pullmans is disinfected; screening against flies and dust and a ventilation system is provided; dietetic service is offered on its diners. To insure further the health of its patrons, employees are taught First Aid. Hostels are provided at stopover points where employees may find rest and recreation.*

are the individual linen and absorbent paper towels and the individual paper cups. How much this means, especially in day coaches, will be appreciated by those old enough to recall the sick traveler, who in the days gone by, haggard and coughing, made innumerable trips to the water tank and its one tin cup. Scrupulous care is exercised in the selection of pure drinking water. The receptacles in which it is carried must be spotless, and to insure that state, they are steamed periodically; also the water

must be properly iced. The ice must be handled with tongs; never touched by the hand. Neither may a hand touch the inside of the water tank. These precautions are to prevent any possible contamination from the introduction of germs.

Passenger cars are thoroughly renovated after each trip. No cursory swishing of brooms and slushing of scrub water today; instead, the car cushions and carpets are removed, the cars sealed and fumigated and then cleaned by vacuum process. The compressed air removes every atom of dust, germ laden or innocent, that may have settled into cracks or lodged on carvings. Every car that starts from a division point is as clean as when it came fresh from the builders.

Sleeping cars naturally come in for extraordinary cleansing efforts. The linens are cleaned in the most modern of laundries and come back as fresh and clean as heat and water can make them. Mattresses, blankets, and pillows are cleaned, aired, and disinfected. The Canadian Pacific uses three sheets on each berth, two to sleep between and the third over the blanket, thereby keeping the blanket from contact with the sleeper's body.

While in use, all cars are carefully ventilated, and in sleeping, dining and parlor cars electric fans are installed for the traveler's comfort. Strict attention is demanded in the matter of maintaining even temperatures. Em-

Courtesy Canadian Pacific.

Travelers who view the beauties of Lake Louise in the Canadian Rockies need have no thought of their physical well-being enroute. Rigid sanitary rules of the Canadian Pacific Railway insure cleanliness on all cars whether coach, Pullman, or diner.

ployees must see that the temperature remains as nearly as possible at 70 degrees during the day and between 60 and 65 degrees during the night. Overheating must be especially guarded against. During extremely cold weather, sleepers and parlor cars are fitted with triple windows and an extra blanket is hung over the windows after the berths are made up to guard against possible drafts. Experienced travelers claim that greater comfort is to be had in Canadian Pacific sleepers in cold weather than on sleepers farther south where less protection is provided against the rigors of winter.

Nowhere in the world do travelers enjoy the comforts en route that they do in America, and that means Canada, too. True, one must pay extra to travel in Pullman, standard, buffet, parlor, or observation cars, but the additional comforts gained by so doing amply repay the extra cost. Dressing rooms on these cars embody every known device to render dressing and travel easy. Liquid soap is supplied through individual containers; linen towels, individual of course, are furnished in abundance; dental lavatories have abolished the old nuisance of cleansing the teeth in wash basins. All these conveniences, as well as the cars, are kept as free from dust and soil enroute as constant attention and polishing by the porter can effect. Adequate screening is provided to

guard against the entrance of flies, mosquitoes, and other insects in season. This measure insures not only comfort, but protection from possible germ-laden carriers.

Sweeping en route must be done with a vacuum cleaner or, where that service has not been installed, with a brush and dustpan, to prevent the flirring of dust. Brooms are abolished. Porters are trained to remove accumulating dust with soft cloths which do not scatter the offending

item as did the old time feather duster. Strict rules forbid the use of water in toilet hoppers for scrubbing or mopping floors. Fresh water obtained from unquestionable sources must be used. Neither may the cloths, sponges or brushes used in cleansing cuspidors, be used in cleaning any part of a car. The most far-seeing and stringent of rules are promulgated and the close oversight of superiors together with the threat of instant dismissal for infraction of said rules insures faithful adherence to them.

In the case of dining cars, the same care is exercised in cleaning, heating, and ventilation as with sleepers, supplemented by extra care in guarding the preparation and service of food. Each chef has a personal pride in his tiny kitchen and its array of shining cooking utensils. "Cleanliness" and "Purity" are the watchwords of each dining car chef. These two attributes must be applicable to the food even from its original source of supply. Therefore, commissary storerooms, cold rooms in which meat, fish and poultry are kept until needed, and butcher shops must be kept absolutely clean and well ventilated. Not only this, but supplies are bought only from sources known to be clean and sanitary.

#### Dining Car Dietetic Service

The dining car conductor is also a dietitian, ready to make suggestions for a selection from the menu. Here is a concrete example of his helpfulness. A certain passenger, who was feeling somewhat indisposed

Courtesy Canadian Pacific.

Great care is exercised in cleaning dining cars supplemented by additional care in guarding the preparation and service of food.

and had no desire for heavy food, ordered fish and milk. The conductor politely informed her that this was an unfortunate combination in her condition and selected something else for her. As she left the car, he said to her, "If you do not feel better in an hour or so, come back to this car and I'll fix you up a drink that will help you." His courtesy was most heartily appreciated.

In order to attain the most sanitary and hygienic service, foods in individual containers are purchased whenever practicable for diners. Cereals in small cartons, marmalades, jams and preserves in single, but generous single portions, ice cream in individually wrapped portions are some of the items so served. Whether one orders oysters on the half shell or oyster stew on a Canadian Pacific diner, he may be sure that they will be only the best shell oysters. We all know that the oyster, once released from its shell, dies, and no matter how carefully kept in bulk, it cannot be as fresh as the oyster on the shell. For this reason, only shell oysters are served whether for frying, stews, or soup.

It has been said that Canadian Pacific diners do not carry can openers. They have no use for them. Canned goods are taboo. Everything served must be fresh from the farm, or garden, ranch, lake, or ocean.

Perfect sleeping and dining car service is only possible where the employees are healthy and contented. Every man serving on these cars of the Canadian Pacific must have a clean bill of health. Company doctors are located at all divisional points to examine employees who do not feel well or who show the slightest indication of disease.

Contentment can only be attained from satisfactory working conditions and adequate remuneration. The Canadian Pacific is noted for the liberal wages paid and is one of the pioneers in providing clean, healthy quarters for employees laying over from home station. At all lay-over points such as Winnipeg, Calgary, and Vancouver, the company has built large hostels which are run along the lines of the Y. M. C. A., being provided with shower and plunge baths, sleeping quarters, reading and writing rooms, in charge of a competent caretaker. In the early days of railroading when employees were away from home there was no place for them to spend their spare time, except in hotels and saloons, often far from clean, where they

Courtesy Canadian Pacific.

The crèche in Vancouver Station, maintained by the Canadian Pacific, has proved a blessing to traveling mothers.

frequently spent all their earnings and were not always in the best of condition to perform their work when they returned to duty. Through the foresight of the manager of the Sleeping, Parlor and Dining Car Service, this deplorable condition has been overcome, and clean, healthy environment is provided in the company hostels. The result is that employees are always ready and efficient to render the very best service.

A constant endeavor to devise new mechanical contrivances that will further the safety of travelers is being made, and employees are encouraged to use their wits and talents along this direction. One of the newest inventions adopted by the Canadian Pacific is a small but valuable item, a track torpedo which functions in three ways. When exploded by a passing train it gives forth a loud detonation, a vivid flare, and a pungent odor so that there is practically no possibility of the warning going unnoticed.

Lessons in First Aid are made available for employees and the knowledge thus acquired is often of great value, particularly among the employees themselves. For instance, a porter slipped and fell under a train which almost severed his leg. He would surely have bled to death but for the timely assistance of another employee who, through his First Aid knowledge, was able to stop the flow of blood thus saving the porter's life, the doctors declared. This general knowledge among the trainmen of "what to do" in the event of an

accident or sudden illness on the part of a traveler is a comforting assurance to prospective tourists who are inclined to worry.

The public in general only notes the efforts made by the railways for its comfort and health, when they are brought to its attention by a cessation of some feature of the system. It takes for granted the smooth running and efficient service, little realizing the wheels within wheels and minute details that are ever working to protect its health and insure its comfort while traveling.

### American Medical Association Elects Officers

Dr. R. L. Wilbur of Stanford, Cal., president of the Leland Stanford Jr. University, was elected at the St. Louis session May 25 as president of the American Medical Association. He will assume office at next year's convention, which will be held in San Francisco.

Dr. Willard Bartlett of St. Louis was named vice president-elect. Dr. Alexander R. Craig of Chicago was re-elected secretary, and Dr. Austin A. Hayden of Chicago was chosen treasurer to succeed Dr. William Allen Pusey of Chicago, who had held the post thirty years.

Dr. F. C. Warnshuis of Grand Rapids, Mich., was elected speaker of the House of Delegates. As vice-speaker he presided at the present session of the House, due to the death last October of Dr. Dwight H. Murray of Syracuse, N. Y. Dr. Rook Slyster of Wisconsin was chosen vice-speaker.

## How Modern Medicine Is "Different"\*

THE author's childhood days were spent in a rather large medical center, where the tall, benevolent physician who took care of the children with scarlet fever, after previously having brought them into the world, who took care of the adults when they were sick, who was surgeon for the railroad company, served also as coroner's physician. Tall, gray bearded, with a long frock coat, he made an impression which in prep school days was visualized in the form of Coleridge's "Ancient Mariner," for, despite the absence of the glittering eye, he always seemed to have time to talk and tell tales of his busy life. The bearded physician is still seen, but more often on the stage than off. Usually smooth-shaven, young "at least in appearance" the physician of today is hard to distinguish from any other man of affairs. Is this only a superficial characterization, or does it really mean that modern medicine is different from the medicine of our childhood days?

### Doctor's Day Is Index

Perhaps the best method of learning what modern medicine actually means, what is necessary properly to perform the healing art, is by following the busy physician through twenty-four hours of any day. In speaking of the "healing art" emphasis is placed entirely on the point of view of the patient, ignoring for the time being the many extensive fields of investigation which have served to differentiate present practice of medicine from that of the past.

That there are two distinct sides to medicine as a science is, of course, appreciated by any student of modern biological methods; but that a large amount of the so-called scientific or laboratory work in medicine has to do directly with proper treatment of the individual patient is a truth not generally recognized by the public, often not by physicians themselves. But the great tendency in modern medicine today in the actual treatment of disease is to follow the dictum that the patient has a disease and not that the disease has a patient. Many of the present popular cults in pseudo-medicine are founded on the neglect of this principle by the

medical practitioner. Imaginary illness does not exist. Pains for which no cause is found are still pains to the complaining patient. It is to be noted that instead of representing the primary insult of the disease-producing agent, the disease picture represents but the reaction of the individual to that reagent. It is almost an axiom to say that no two persons will react in the same way to a given pathological insult any more than they will react in the same way to a book, to the Peace Treaty, or to Mrs. Parker's descriptions of the I. W. W.

### Individual Reactions Vary

As an instance of variations in individual reaction, one may cite almost any two cases of so-called shell shock or war neurasthenia. Here the reaction may be entirely psychic, the type of response depending almost entirely on the previous emotional history of the individual soldier, or it may simulate many varieties of organic disturbance. In the more purely physical realm two people may be exposed to the same bacterial disease, such as pulmonary tuberculosis, one an Irish policeman and the other a Jewish shop worker. The former is normally robust and healthy, well nourished, and accustomed to exposure to the elements; the latter is likely to be undernourished, underfed, unacquainted with sunshine, and often a stranger even to fresh air. Exposure of the two to the same strain and the same dose of tubercle bacilli and the prognosis for the two patients will be just the opposite of what is expected for the Jewish shop worker runs perhaps a fifty per cent better chance of recovery than does the Irish policeman. Surprising as this may sound, there is abundant statistical evidence proving the truth of the statement, the reason being that the Jewish race has established a racial immunity and the Irish has not.

Following the physician in his daily rounds, wherein has the position of the patient been changed by the more recent methods of practice? A clinic at 8 a. m. starts the day's work, and for one and one half hours the medical students of today are taught in the hospital at the bedside of the patient. Again individual patients are brought before the student, who is given the opportunity of examination, history taking, and discussion. From student days onward there is a radical change. The student is now

taught to think for himself rather than to listen to and accept uncritically the words of the masters. The student must weigh the evidence so that when he, too, becomes a physician he can know how to give his patient the best.

Medicine today is more intensive in its application and more extensive in its scope than it has ever been before. The intensive application of modern medicine at the bedside is, of course, nothing new in principle and has been practised for years by good physicians even when the methods applied were limited to those found in a country village. In the extension of the boundaries of medicine there is, however, something new, if not in principle at least in the fields to which it now extends.

### Physicians' Wider Interests

Not only must the physician of today know the social position, the home conditions, and the status of the family budget of the individual patient, but physicians as a whole are more widely concerned with prevention of disease by means of social legislation, by regulation of hours of labor, and by the multitudinous other activities which engross the mind of the intelligent public. It is rare, indeed, that the influence of the medical profession is not in evidence in almost all big movements dealing with the general welfare of society. The change of the Fourth of July celebration from a wild and tumultuous orgy of fireworks and lockjaw, destruction and death, to a sane and sensible realization of the meaning of the day may be directly attributed to the influence of members of the medical profession who believed that the annual waste of life was an unnecessary and quite undesirable evil. In Illinois the gubernatorial commission to study the condition of women in industry contained three physicians out of a total of seven members.

Ward rounds! The ward offers a collection of suffering humanity who only too frequently are suffering from preventable, not to say inexcusable defects in modern methods of living and work. Realizing this, the physician cannot longer be satisfied with a hasty examination, a scribbled prescription, and a hurried visit to the more lucrative patient of the private rooms. Why is the patient in the first bed ill? What is his complaint? What is the diagnosis? What is the

\*The fourth of a series of articles on "Popular Medical Misconceptions," beginning with the March issue of THE NATION'S HEALTH.

fundamental cause of the illness? What the remedy? And how prevent his re-admission to the hospital? The history is obtained by careful painstaking inquiry, but the physician is not satisfied with the information given by the patient alone. The patient may not be willing to disclose certain things about his family life, or his manner of living, and so the social service department brings out the fact that the man has a sick wife and that he, in addition to working hard every day, is up a good part of the night looking after his family.

### A New Perspective

His complaints are vague, indefinite, rather difficult to interpret, and a thorough physical examination fails to reveal a straight-cut clinical picture. It is here that the modern physician departs from the traditional path and applies to his individual patient the accumulated benefits of the more recent scientific investigations. It makes no difference what line of investigation is indicated, whether it be one of those fascinating heart traces obtained by the electro-cardiogram, whether it be an extended series of moving pictures of the stomach and intestines, a study of the function of the kidney by means of an elaborate chemical analysis, or what not, everything is done for the patient.

Whether in clinical investigation, or research, or scientific medicine, the point is that the patient receives the benefit of it all. This point should be emphasized because it seems that too many people do not grasp the idea that there can be no line of cleavage between scientific research, and treatment, between the laboratory and the patient. The charge has been made that medical practice has become so complicated, that a man must not only specialize in diseases of a certain part of the body, but if he wants to be really thorough, he must specialize in one disease or in the diseases of one organ. This, of course, is only a Shavian truth, for although it is true that it is not within the power of most men to grasp in detail all the intricacies of modern medical science, it is by no means necessary for him to do so. He must have an interpretative mind and an ability to utilize facts established by methods which he need not understand. If accumulated data already obtained do not appear to explain the symptoms of which the patient complains, he must be in a position to call to his aid his colleagues, men who have developed themselves along lines which lead to a different point of view of the

patient and who may give an angle of insight that is missed by the first man. More evidence is thus accumulated and finally, the patient's story is complete. Cause and effect are often brought together as dramatically as in the sequence of Poe's stories. From the very nature of the methods employed the sequel of the patient-story which in this instance is called treatment, is thereby plainly and clearly indicated.

Treatment involves the successful relief of the patient's illness and prevention, when possible, of recurrences of the same complaint. And here the two phases of medicine which we have already spoken of, namely, the psychology of the individual and the social status, are carefully and thoroughly investigated. Mitral insufficiency is a leakage of the heart valves, a disease which diagnosed early and handled properly need not incapacitate a man from future wage earning even though his wage earning may be limited. To the rich the treatment of mitral insufficiency is a simple matter of life regulation, of vacations, but to the poor in the past the condition has been only too often the cause of repeated breakdowns and a series of hospital visits. The ward patient with mitral insufficiency, therefore, who enters the hospital with the complete heart breakdown, presents the question of how to prevent subsequent similar occurrences? The man is anxious to support his family. There are, indeed, few men who enjoy support of organized charity, be it state or private. Yet he has learned that every time he works he gets sick, and he knows full well that if he keeps it up the ultimate end will be complete incapacitation and death. Social service again supplements medical care and the man is referred to the dispensary heart clinic, where the treatment instituted in the hospital is continued, and where his capacity for other types of work than the one which caused his breakdown is carefully investigated. If necessary, he is taught a new trade. The stevedore becomes a basket weaver, and, although during this period a man and his family may necessarily become the objects of support by organized charity, it is not very long, speaking from the point of view of a man's life, before he again becomes a wage earner, frees himself from the necessity of repeated hospitalization. The stigma attached to pauperization is lifted and he becomes a wage earner, a free man. Restoration of social function becomes the objective—whether the affliction be diabetes

or neurasthenia, tuberculosis or occupational neurosis, the physician of today aims to return the man, perhaps made sick by social neglect, back to society able to carry on the burden of life. That not all patients can carry on well is, of course, in the nature of things essentially true; but that a large percentage of handicapped are returned is now a matter of statistical history. In certain industrial organizations today various jobs have been analyzed in such a way as to make it possible for an industrial physician to fit men or women partially handicapped into jobs which they can perform as completely as a fully normal individual. Difficult as is the problem of industrial regeneration of the individual patient, it is the real object of treatment. It makes not one iota of difference how purely scientific in its researches an institution may be, how intensive the investigative work, modern medicine connotes the extension of the institution's activities into the very fundamentals of a man's existence, if such extension is necessary for rehabilitation.

### Care for Middle Class

One criticism of modern medicine which has been discussed and which is being discussed more freely all the time, is that the best practice today is open only to the rich and to the poor, but that without either pauperization or indebtedness, the great middle class finds it difficult to obtain what the very poor can obtain in medicine. This situation is being met by a definite effort of reorganization so that the middle class can receive the best modern medicine gives without losing its self-respect or going in debt for life. At present the fees, necessarily large, for special investigation are not, generally speaking, so graduated that the man who cannot afford the whole thing can pay part. This is true of the hospital room, trained nurse, just the same as it is true of the special investigation. Usually the better physicians are available, if not for house calls, at least for hospital work, at fees consistent with the income of the patient; but the hospital finds that it cannot afford to reduce rates for its pay patients without larger endowments than hospitals now have, and the nurse, whose entire income depends on her momentary case, finds it impossible to reduce her fees. That something must be done to remedy this condition is a recognized fact which is receiving the careful attention of those interested in an extension of the best medical practices to the general community.

# Cities Provide Popular Summer Recreations

## Playgrounds, Camps, Swimming Pools Furnish City-Bred Health and Fun

BY HELEN SEDGWICK JONES, COMMUNITY SERVICE, NEW YORK CITY

**S**URE, we're going to win! remarked the wiry, freckle-faced youngster. "We're all in fine trim and Bill's new bat and glove work just slick. We tried 'em out yesterday."

It was a hot day in July and the possessor of the freckles had acquired them through a short succession of summer seasons filled with just such activities as the one now in view. He was healthy and happy and too busy to get into mischief. The secret of it was that his city had realized that boys and girls had nothing definite to do in the summer when school was out and had therefore provided them with playgrounds and athletic fields where they might have a chance to work off their surplus energy.

Many other cities have had the same foresight! Some have gone even farther and provided golf courses and summer camps and community buildings so that the fathers and mothers as well as the children may have an opportunity to play. Money has either been appropriated from the city funds or donated by private citizens for the purpose of building and maintaining these facilities and a recreation commissioner has been employed whose sole business it is to see that the facilities are used and that wholesome recreation activities are carried

on—in many cases, during the entire year.

But play truly comes into its own in the summertime when the great outdoors calls to young and old to come out and play. During this season the playgrounds and athletic fields in most cities are kept open from nine to six during the day and often times in the evening. Sandboxes, small swings and slides, teeters and a wading pool are reserved for the toddlers. More castles and cities are built by tiny hands on American playgrounds each summer than were built in a century when knighthood was in flower. And during June, July, and August, what is more refreshing to little feet than to paddle through the cool water of a wading pool or a boat-sailing pond? Such refreshment, many cities serve.

### Real Play Houses Provided

Larger swings, teeters, and giant strides are available for older boys and girls. In the open spaces folk dancing and such games as volley ball, captain ball, and baseball are conducted by play leaders.

Playing house is a summer vogue with certain ages, just as it always has been and ever will be. And it is commendable to find the dignified playground authorities in one city

supplying the demand with honest-to-goodness playhouses. In the parks in Hartford, Conn., there are whole villages of tiny dwellings four feet high, with canvas roofs painted bright red, each furnished with a small wooden table, four wooden chairs, and a set of wooden play blocks. The wire netting which forms the sides of the houses lets in the sun and air and the green grass makes a soft and velvety carpet. Here both boys and girls may be found carrying on all sorts of community activities—running department stores, carpenter shops, going to church, attending weddings, making social calls, and doing many other interesting things that the oldest of the grown-ups do. All nationalities are represented and many social facts and customs are learned through the activities carried on in these tiny villages.

Where there is a municipal swimming pool or bathing beach, swimming meets and water carnivals are very popular. Sometimes the whole community unites with much enthusiasm in a program of water contests, games and sports which are open to all ages.

Smaller towns, especially, go in for play picnics, play days or play festivals, with athletic programs in which the whole community takes part. Out-of-door pageants are given, in which sometimes as many as two or three hundred people perform. Our bombastic Fourth of July of yesterday, is more and more giving way to this sort of celebration, leaving this red letter day less marred by the kind of accidents which formerly attended it.

During the last year or two roller skating meets have become very popular as a summer pastime. Not long ago a city-wide meet was held in Greenville, S. C. Anyone from eight to sixty years of age was permitted to enter one or more of the seventeen events. There were two hundred entries and one hundred spectators, two-thirds of the crowd taking part. The affair was so successful that Greenville plans to make the roller skating meet an annual event.

Kite tournaments call for the kind of ingenuity and skill which shows up

Courtesy Community Service.

Hartford, Conn., provides these tiny dwellings in its parks to satisfy the natural desire of every child to play house.

Courtesy Community Service.

Wading pools attain popularity with the younger citizens.

best as the thermometer ascends. In Chicago and in Middletown, Ohio, kites of all shapes and sizes are entered in annual kite tournaments. Much excitement is aroused. Prizes are awarded the makers of the best kites and especial honor attaches itself to the victors in the annual kite-battles in the clouds.

#### Pet Shows Are Popular

When it is too hot for so much excitement, many groups of children turn to quiet games or stories. Wonderful tales are told each season by play leaders or by "gypsies" who come on to the playgrounds and play streets in some municipalities dressed in bright colored dresses and jingling jewelry. Basket-making and sewing are other diversions opened to many girls, while boys are afforded opportunities to make tin-can toys and furniture.

Sometimes a pet show is held on the playground. This gives each boy and girl a chance to show off a much admired pet. At the show held last summer in Lexington, Ky., a surprising variety of live stock was exhibited including bears, wolves, alligators, coons, cats, dogs, birds, possums, snakes, and gold-fish.

The extra hour afforded by daylight saving in a number of cities has meant an extra hour of fun for the men and women who spend the greater part of their time earning the means whereby to subsist. Baseball, handball, volleyball, and tennis leagues have been organized and the game tournaments have been played off amid much enthusiasm during the twilight hour. The anticipation of strenuous open air exercise at the end of a day shortens hours of monot-

onous routine which otherwise might seem unbearable.

A twilight baseball league has been started in Visalia, Cal. Only men over eighteen years of age are permitted to become members. Districts, rather than picked teams, play against each other and the interest aroused has made new friendliness among many individuals. Whether the games are enjoyed or not may be judged from the remark of one member who was heard to say one morning: "My team lost twenty-six to four last night, but what's the difference—it's all in the fun of playing. Why, I'd give them a dollar a game just to let me play."

Horseshoe pitching or quoits—the game our fathers and grandfathers and great grandfathers played—has enjoyed a revival the country over during recent years. Interest in this

sport is especially keen in Long Beach, Cal., Minneapolis, Minn., and Zanesville, Ohio. In Zanesville, a league has been perfected and the city divided into four sections, each represented by sixteen teams. Members have been recruited from industrial plants, fire engine companies, churches, and civic and social organizations. Last summer a city-wide tournament was held at the county fair and the season wound up with a tournament and barbecue.

Community singing in the parks or band concerts invite the attention of music lovers and musicians during summer evenings. Outdoor dancing pavilions where splendid music is furnished are provided by some cities. Inconspicuous supervision is supplied, and ten or fifteen cents will allow a person to dance the entire evening. These dance pavilions are very popular and in one city the vicious dance resorts which formerly drew so many of the young people have been entirely abandoned.

#### Gardening as Recreation

Professionals in the business might not call gardening a recreation but to the man or woman weary from bending over a desk, who longs to get "next to nature," or to the boy or girl who takes pride in watching things grow and finally develop into real produce fit for canning or sale, there is certainly a genuine enjoyment in this form of activity. Detroit's recreation commissioner says "People in cities live an artificial life, forgetting the wonders of nature. Gardening helps to bring them back to nature. When one is close to nature, he is rested and receives recreation." Over

Courtesy Community Service.

Horseshoes has been revived as a popular pastime in some municipalities, notably Long Beach, Cal.; Minneapolis, Minn., and Zanesville, Ohio.

Courtesy Community Service.

Well rolled tennis courts are maintained by many cities and are seldom seen empty during the summer months.

twelve hundred children watched their own gardens grow in Detroit last summer and raised over seven thousand dollars worth of vegetables. In some cases, whole families were granted garden space by the recreation department.

All these activities go to make life more worthwhile during the weeks of strenuous work but there comes a time when work is suspended for a week or two and the chance to take a real vacation is at hand. Those who are fortunate enough to have an automobile in which to spend their vacations will find auto camps fitted up for their express pleasure in many cities. Shade, shelter houses, electric lights, ovens or stoves, free gas or firewood, sinks for washing dishes and laundry, tables and chairs, and swings and slides for the children are

afforded on these camping grounds. A fee of from twenty-five to fifty cents a day is charged and a time limit of from one to two weeks is usually put on the stay of any one party. Strangers are thus made to feel at home and the city in turn is far-famed for its hospitality.

#### Cities Provide Camp Grounds

There are many, however, who have little money to spend for this vacation yet it is altogether desirable that they, like their more fortunate brothers, should have the benefit of a change. Several cities have recognized this need and have provided camping grounds, fitted up with recreation facilities and provided with a staff of helpers and guides, where people may go at small expense. Those near Los Angeles are prob-

ably the most noted. They are situated in the mountains far above the heat and crowds of the city. Last summer, four thousand Los Angeles people, men, women and children, spent their vacations in these camps. A little booklet on Summer Camps issued by Community Service, 315 Fourth Avenue, New York city describes the groups of campers who use this recreation space as "composed of citizens from every walk of life." An adult pays from \$14.25 to \$16.50 for a thirteen-day outing; children over five, \$12.50, toddlers \$6.50 and babies \$3.00. While there, they live in cabins built in the shade of tall fir trees and cedars; eat their meals in a big open air dining room; and at night play games, tell stories, and sing songs around the camp fire. They may read, go swimming in the swimming pool, fish, hike or play hockey, volley ball, or baseball on the big athletic fields. In short, whatever wholesome recreation they desire to choose is near at hand inviting them to participate. Thus they come back to work in the city re-created in mind and body.

Each year more and more cities are providing recreational facilities for their citizens. They have found that recreation pays in health, in happiness and in better citizenship on the part of their people. And they can't be blamed if they feel a spark of self-conscious pride when they hear one of their coming citizens remark to a youthful stranger in the community "Aw, wha' d'ya t'ink? This ain't no dead town! There's a swimmin' race or a ball game or somethin' else that's fun for us fellas to do here all the time—summer 'specially."

## Faulty Foods and Gastro-Intestinal Disease

IN CERTAIN Himalayan races gastro-intestinal disorders do not exist and the abdomen sensitive to nerve impressions, to fatigue, anxiety, or cold is unknown. Their "buoyant abdominal health" in contrast with the dyspeptic and colonic lamentations of western peoples constitutes the burden of a lecture delivered recently by Robert McCarrison at the University of Pittsburgh. These races are of magnificent physique, preserving until late in life the characters of youth. They are unusually fertile and are endowed with nervous systems of marked stability. Far removed from the refinements of civilization, their mode of life offered a fine field for the special

study undertaken by McCarrison in a deficiency disease inquiry undertaken for the Indian Research Fund Association. During the entire period of his association with these people McCarrison never saw a case of atrophic dyspepsia, of gastric or duodenal ulcer, of appendicitis, of mucous colitis, or of cancer, although his operating list averaged more than four hundred operations a year. The cases in which attention was directed to the viscera were of the rarest, their consciousness of this part of their anatomy, as a rule, relating solely to sensations of hunger.

Searching for an explanation of this difference in the incidence of gastro-intestinal disease in the two peo-

ple's McCarrison attributed it, in the main, to four circumstances: (1) Infants are reared as Nature intended them—at the breast. If this source of nourishment fails them, they die; and at least are spared the future gastro-intestinal miseries which so often have their origin in the first bottle. (2) The people live on unsophisticated food of nature; milk, eggs, whole grains, fruit, and vegetables. Not one in a thousand of them has ever seen tinned salmon, chocolate, or a patent infant food; less sugar is imported into their country in a year than is used in a moderately sized hotel in a single day. (3) Their religion prohibits alcohol and, although they do not always lead in this re-

spect a strictly religious life, nevertheless they are eminently a teetotal race. (4) Their manner of life requires the vigorous exercise of their bodies.

To a study of these differences in the habits of the Himalayans as compared with western peoples McCarrison addressed his inquiry, and the discourse reported in the *Lancet* of February 4, 1922, concerns itself with the first two factors and affirms on unequivocal evidence that the two chief causes of disease and death are food and drink.

The same sources of foods are utilized by civilized man as by these primitive peoples, but with what a difference! One way or another, by desiccation, by chemicals, by heating, by freezing and thawing, by oxidation and decomposition, by milling and polishing, he applies the principles of his civilization—the elimination of the natural and the substitution of the artificial—to the food he eats and the fluid he drinks. With such skill does he do so that he often converts his food into a "dead" fuel mass, devoid of those vitamins which are to it as the magneto's spark to the fuel mixture of a petrol-driven engine. Unmindful, too, or more often ignorant, of the composition of the fuel-mixture with which he charges his human machine, he joins deficiencies of some essentials with excesses of others, heedless of the intimate relation of bodily balance to these food ingredients.

In food imbalance the gastro-intestinal tract is the first to suffer. Disorders of digestion, absorption, and assimilation are the signs that our ship is running on the rocks, and as good pilots we must be aware of them. McCarrison charges that we are apt to assume more readily the offices of salvors of such wrecks than of pilots whose function is to prevent them.

Not only is the functional failure of the digestive system an early evidence of faulty food, but the gastro-intestinal tract is often the first to exhibit evidence of infection by pathogenic germs because of it. Food is taken into the body to repair tissue waste, to supply energy, and to provide the medium for the chemical reactions of the body. It is not necessary to make laboratory experimentation to prove that if a woman lives on white bread, artificial foods, and tea, with a minimum of meats and green foods, she is prone to suffer from such digestive disorders as dyspepsia and colonic disease. Such a diet favors the development in the digestive tract of fermentative organisms, and makes relatively more deficient the vitamins necessary to healthy cellular action: nor does it contain a sufficiency of vegetable residue, of cellulose, waxes, and vegetable salts to insure natural action of the bowels.

Among the dietary faults incriminated McCarrison enumerates: (1) the tendency in modern times to rear children artificially, on foods inferior not only in vitamins, but enzymes, thyroid derivatives, and other essentials; (2) the comparative rarity of fresh fruit and the scantiness of green vegetables even on the tables of the rich; and the methods of cooking which extract their vitamins and salts; (3) the use of stale foods involving the introduction of factors incidental to oxidation and putrefaction.

The frequency with which deficient and ill balanced foods are used is most apparent when the diatetic habits of persons in subnormal health are considered. Prejudice, penury, ignorance, habit—often prevent the proper use and choice of health giving foods. Who is not familiar with the spoiled child among well to do classes, unhealthy of appetite, pasty in complexion, who, deprived of the necessary ingredients of a well balanced natural food, craves chocolates and other dainties so much used to excess? Or with the pale, overworked, anemic girl, static with visceroptosis, acne, or seborrhea, and oftentimes with vague psychoses who subsists chiefly on white bread

and tea? Or with the languid lady, devoid of healthful occupation, who deprives herself, for some imaginary reason, of substances essential to her well being? Some live in luxury whose ignorance or fancy debars from choosing the food aright.

Latterly many have been inclined to assume a "too-vitamin" attitude toward the diet. It is safer at all times to place the stress on the well balanced ration. It is unwise to consider any of the essential ingredients of food, whether carbohydrates, fats, salts, water, or vitamins as independent of the assistance derivable from their associates in maintaining digestive and nutritive function. No doubt some of these have special relations to others, as, for instance, that of iodine to fats, that of vitamin B to carbohydrates, that of vitamin A to lipoids, calcium, and phosphorus-holding substances, and that of vitamin C to inorganic salts.

In campaigns for efficient feeding it is to be emphasized that the ranks of the deficiently fed do not include only infants and children, nor does access to abundance of food necessarily protect from food deficiency. The first need is to instruct the masses as to the food requirements of the body, and then to apply the results of science to the production of natural foods in abundance and to their widespread and cheap distribution rather than to the erection of institutions for the treatment of maladies due to their want.

## Centenary of Bretonneau

MANY of the American medical officers who served over-seas during the World War will remember with pleasure the very artistic monument in the Place Emile Zola, opposite the venerable Cathedral of Tours hallowed by some of the stirring events in the life of Joan of Arc. They will recall the beautiful bronze figure of Tours enthroned and in the act of crowning with laurels three of her sons whose heads appear in bas-relief on a plaque affixed to the pedestal below. Those who took the trouble to decipher the names of these heroes read the words, Bretonneau, Trousseau, and Velpeau, and those who visited the art gallery in the Archbishop's Palace a stone's-throw away brought away with them an appreciative memory of the painting of the latter operating in his surgical clinic at Paris. Velpeau is a

name known to all physicians, some know something of the brilliant Trousseau, but of Bretonneau, whose apostles they were and to whom the entire world of medicine owes an enormous debt, few know anything at all. Yet it was he who ushered in and prepared the way for the discoveries of Pasteur and who deserves first rank among the men of genius who by their brilliancy and the importance of their work have illumined the route of scientific progress.

Recent French medical journals announce that, under the auspices of the School of Medicine and Pharmacy of Tours, there is to be held a centenary celebration on June 24, 25, and 26 next, to do homage to the memory of the great clinician and epidemiologist, Pierre-Fidèle Bretonneau, who in 1822 set forth the doctrine of the specificity of disease, thus

giving to the science of medicine an enormous forward impetus and directing its progress into a new path for the everlasting benefit of the human race. A modest physician, beginning his professional life as health officer of the market-town of Chenonceaux and practising later in provincial Tours, too busy with his researches to give afterthought to glory or renown, neglecting to publish many of the results of his observations, never receiving the official title of Professor de Faculté, never having more than a dozen students at a time, he was nevertheless able to make discoveries which reversed the scientific dogmas of his time and to stamp his genius indelibly on such men as Trousseau, Volpeau, Goraud, Moreau de Tours and Baillarger. His early work as a health officer naturally turned the current of his mind to the epidemic and contagious diseases and he devoted himself chiefly to the study of two of the most redoubtable infections which attack infancy and adolescence, diphtheria, and typhoid fever, to both of which he gave the names which they now bear. He made a study of the affections of the throat and pharynx and recognized the symptom-complex of diphtheria in 1821, and the following year he classified typhoid fever as a separate disease entity always characterized by the same pathological lesions, and localized at the same point.

While he was still at Chenonceaux, he observed that the fluids secreted by the canthorides and other biting insects provoked a skin lesion which varied according to the species of insect. He concluded that the product of the secretion of each species is specific and always produces the same organic lesion. Applying this method of thought to human medicine, he evolved the doctrine of the specificity of disease. This work, which has never been published but which will appear in print in connection with the forthcoming celebration, would probably have remained forever hidden had it not been for his devoted pupils Trousseau and Volpeau. It is difficult for us of today, living as we do in an age when every school child accepts as an article of faith the bacterial causation of disease, to realize the enormous importance of the principles which Bretonneau laid down and the gigantic scientific courage which their evolution represents. They were embodied in two statements whose clarity and precision merit the admiration and respect of all ages. (1) That each

disease is determined by a special living being foreign to the individual.

(2) That this living being always produces similar inflammations, that is to say, specific. He compared this living being to an entozoa, thus foreseeing and announcing the microbial theory thirty years before Pasteur.

Some of his aphorisms in support of his doctrine are equally illuminating:

A multitude of inflammations are determined by material, extrinsic causes, by purely poisonous beings from without and certainly foreign to the normal state of the organic structure.

It is the cause which stamps a lasting, particular characteristic upon the inflammation.

Each disease runs through various periods in a determined time and fol-

lows a constant and regular order in the development of the successive phases.

One should consider as specific every kind of inflammation which presents constant characteristics and possesses the property of transmitting itself from one individual to another.

During the centenary celebration, a suitable plaque will be placed upon the house where he was born in 1771 and where his ancestors practiced surgery in the tiny market-town of Saint-Georges-sur-Cher (Loir-et-Cher), while in Tours, to whose general hospital he devoted himself until his death in 1862, there will be held appropriate ceremonies to honor the man who with Laënnec, Bichat, and Cruveilhier at the beginning of the nineteenth century founded contemporary French medicine.

## New England Health Institute

By JOHN T. BLACK, M.D., COMMISSIONER STATE DEPARTMENT OF HEALTH, HARTFORD CONN.

THE New England Health Institute held in Hartford, Conn., May 1 to 6, 1922, one of the regional institutes suggested by the United States Public Health Service, reached a total registration of 850, and this despite the fact that several conflicting meetings were in progress at the same time. Three lectures were scheduled for each hour from Monday at 3 p. m. to Friday at 5 p. m. The average attendance by courses was as follows:

I Health Administration . . . . .	100
II Preventable Diseases . . . . .	150
III Sanitation . . . . .	50
IV Tuberculosis . . . . .	100
V Venereal Diseases . . . . .	125
VI Child Hygiene . . . . .	150
VII Public Health Nursing . . . . .	200
VIII Social Work . . . . .	150
IX Mental Hygiene . . . . .	100
X Industrial Hygiene and Acci-	
dent Prevention . . . . .	50
XI Food and Food Control . . . . .	70
XII Nutrition . . . . .	125

The seventy-seven faculty members contributed their services and with but few exceptions the program was carried out precisely according to schedule. Highly representative men in their several fields conducted the lectures, among them such leaders as Drs. A. J. McLaughlin, C.-E. A. Winslow, J. E. Goldthwaite, L. Emmett Holt, David L. Edsall, Louis I. Dublin, Merrill E. Champion, Taliaferro Clark, R. M. Allen, A. W. Freeman, L. L. Lumsden, William F. Snow, Richard M. Smith, George E. Tucker,

Professor C. E. Turner, and David Van Schaack. Few clinics were given and these were in Hartford institutions. No elaborate field trips were planned, although the opportunity was given to visit engineering and industrial works. The registration of courses by affiliation is of interest as indicative of the extension of health activities to different institutions. It included:

Health Officers—State and local . .	66
Health Departments—Heads of	
divisions, technicians, etc. . . . .	79
Nurses—Visiting, school, indus-	
trial, etc. . . . .	260
Physicians—Clinic, hospital, in-	
dustrial, etc. . . . .	91
Teachers—College and school . . . .	35
Social workers—including social	
and mental hygiene . . . . .	81
Students—Colleges and schools of	
health . . . . .	55
Miscellaneous—Physical directors,	
probation officers . . . . .	57
Non-affiliated—Persons interested	
in Public Health . . . . .	53

At a meeting of the Advisory Board held during the institute, the following recommendations were adopted:

(1) That the Institute be held annually.

(2) That a registration fee not exceeding three dollars be charged.

(3) That the next meeting be held in Boston or a city in the vicinity, probably Worcester.

(4) That Dr. Eugene R. Kelley be Director for the 1923 meeting.

# The United States Protects Her Milk Supply

## Work of Department of Agriculture Has Made Nation Leader in Dairy Sanitation

BY ERNEST KELLY, IN CHARGE, MARKET MILK INVESTIGATIONS, DAIRY DIVISION, U. S. DEPARTMENT OF AGRICULTURE, WASHINGTON, D. C.

THOSE connected with public health work realize that proper protection of the food supply is one of their most important functions. What is true of the food supply in general is even more true of the milk supply. Milk is an extremely perishable product, an excellent medium for bacterial growth, and is the chief food of infants, young children, and many invalids. In addition, it is often used in a raw state without the application of heat so that existing bacteria are not destroyed.

The United States, has without doubt, led all countries in the protection of milk supplies, and yet it is remarkable to note that as far as known the first laws regulating milk were passed in Massachusetts only about sixty years ago. These first laws took no cognizance of the sanitary conditions of the milk supply but related solely to skimming and watering. These laws were followed by other sections, but it was not until a number of years had passed that any regulation was attempted to safeguard the production and handling of milk from a direct standpoint of the public health. As the science of bacteriology developed and was applied to the dairy industry, legislative bodies began to enact new legislation to control the sanitary quality of milk.

The United States Department of Agriculture early recognized the importance of this line of work and in 1897 started studies on the sanitation of milk supplies. In 1900 a very intensive series of studies was started which resulted in the creation of a market milk section of the Dairy Division in 1905. This section was formed to study problems concerned with sanitary milk production and distribution and to spread broadcast the results of these studies together with the findings of the research laboratories. Later on the demand for this class of work increased to such an extent that a market milk specialist was stationed at Salt Lake City, Utah, to handle the situation in the far west.

During the early days of this work the way was full of obstacles which had to be overcome and there were many discouraging features. The

question of dairy sanitation was entirely new to the dairy farmer and he was full of distrust and suspicion of those who sought to regulate his business. Inspectors and educators were told that the dairy had always been run on the same old lines without any new-fangled notions, that all the children had drunk the milk, and no one had ever been sick because of it. As the work advanced, progress was slow but sure. The specialists of the Department, boards of health,

work of the Dairy Division has been entirely educational and has been divided into these three general groups: (1) Research work to discover the factors affecting the wholesomeness of the milk supply; (2) the suggestion of legislative regulation and methods of enforcement; (3) the formulation of systems of inspection which will be educational, effective, and uniform.

The protection of milk supplies from certain specific diseases has engaged the attention of the Department to a great extent. Without doubt the most important phase of this work is that carried on by the Tuberculosis Eradication division which is encouraging the tuberculin testing of dairy cattle and is cooperating with the various States to stamp out bovine tuberculosis which is transmissible from the bovine animal to the human. The tuberculosis eradication division, through its educational propaganda, the actual testing of cattle, and the establishment of accredited herds which are under Government supervision, has done much to decrease the menace of tuberculous milk.

Research work done by the Pathological and other divisions of the Bureau of Animal Industry has also increased our knowledge of the cause and effect of certain animal diseases. It has sometimes been facetiously said that the Government spends vast sums of money to save hogs and other animals while it spends little or nothing to save children. Such a statement is misleading and untrue. While it may be a little aside from the subject of this paper, it is appropriate to mention that the large bulk of the activities of the Department relating to animal health have a direct bearing on the public health in the protection of meats, meat products, and milk supplies. If we add to this the work done by the Bureau of Chemistry for the protection of interstate shipment of food products, the work of the Dairy Division on dairy sanitation, the work of the U. S. Public Health Service, and that of the Children's Bureau, the Bureau of Education, and other branches of the Government, it can readily be

Milk cooler and insulated storage tank. Experiments have shown the best ways of cooling and storing milk.

and the agricultural colleges spread the gospel of clean milk so vigorously that the influence began to be felt and prejudice was overcome. It is not necessary to trace all of the early steps in dairy sanitation but it may be interesting to point out the main features of the Department's work in this direction up to the present time.

### Work in Dairy Sanitation

So far as dairy products are concerned the Department holds no police powers except that the Bureau of Chemistry is empowered to supervise all food products entering into interstate commerce and the Dairy Division is entrusted with the supervision of manufacture of renovated butter. Aside from these two features the

A graphic illustration showing how the small top pail protects milk from contamination.

reckoned that the Government is making great effort to safeguard the lives and health not only of the infants but of the adult population as well.

Through its research laboratories and the market milk section, the Dairy Division has carried on intensive investigational work on those factors which will produce a low bacterial count in milk. Through its work it has pointed out the essential factors in clean milk production; the clean cow, small-top milking pail, sterilized utensils, and prompt and efficient cooling. In this connection, investigational work is being done on proper cleaning of the milking machine which is becoming a considerable factor in the production of milk for city milk supplies. Investigators have studied various methods of cleaning the machine and have determined a workable method.

### Transportation Problem

Lesser factors, which do not influence the bacterial count of milk to as great a degree as the factors already outlined but which do have a bearing on the wholesomeness of the milk supply, have also been studied. Among these are the proper construction of dairy buildings, such as barns and milk houses to insure that they be simply built and easily kept clean. Working blueprints are sent to farmers for the construction of suitable sanitary buildings. Other things studied have been proper methods of straining milk, sewage and waste disposal, and water supplies.

In the early days milk came fairly direct from producer to consumer, but with the growth of cities, milk has had to travel long distances and pass through a complex system of distribution. Where milk is hauled for any considerable distance, the question of proper transportation is of great importance. For several years the Division has studied different methods of transportation, seeking to find the methods which will bring the milk to the cities in the best possible condition. Such studies have covered proper pre-cooling, different

types of refrigerator cars, methods of icing, elimination of delays in transit, and types of tanks hauled on auto trucks.

After the milk reaches the city, it must undergo a number of processes, each having a direct bearing on its sanitary quality. Probably the chief advance made in handling general milk supplies came about through the introduction of pasteurization. At first pasteurization was carried on at relatively high temperatures for short periods of time and served as a means of prolonging the life of the milk so that it did not sour so quickly. It was soon found, however, that the old methods of pasteurization were not satisfactory, and that pasteuriza-

Clean, healthy cows, well fed and kept in clean surroundings, constitute the first step in clean milk production.

tion at lower temperatures for longer periods of time was best. The Division has recommended a temperature of 145° F. maintained for thirty minutes. Chemical and bacteriological studies have shown that this is the optimum temperature at which no appreciable chemical changes are made in the milk constituents and all disease-producing organisms are killed. Studies have been carried on in city milk plants and many factors learned in the sanitary handling of milk.

Many of the early dairy laws were hurriedly compiled and were based on incomplete information regarding all phases of the subject. As knowledge of dairy sanitation grew, such laws became obsolete and have had to be revised. The Dairy Division has paid particular attention to these. It has been called upon to revise many city dairy laws and to go over tentative ordinances before their enactment

for the purpose of suggesting changes. In general, milk ordinances in the past have been very cumbersome, containing inconsequential rules which served no useful purpose but confused and antagonized the farmer. Other ordinances have been so worded as to be unintelligible. For instance, one city enacted a milk law, which, contained one sentence of nearly 400 words. The Division's constant effort has been to make laws simple, efficient, understandable, and enforceable. Following this line further, with the cooperation of the Solicitor's office, a pamphlet was prepared in 1917 containing suggestions for a model milk ordinance. This "model ordinance" in brief, concise legal form has met a long felt need. The ordinance is variable to suit local conditions, there being no attempt to draw definite chemical and bacteriological standards, as it was the belief of the Division that such standards should be set only after a very careful survey of local conditions.

### Educational Inspection

Realizing from the beginning the importance of educating dairy farmers rather than coercing them, the Division has always aimed to develop a system of dairy inspection which not only secures results, but lasting results. As the old motto goes, "A man convinced against his will is of the same opinion still." Of course, certain dairymen who wilfully and repeatedly violate laws have to be brought to account for their doings, but if they can be educated to see the reasonableness and the necessity of laws, the results obtained will be permanent. The Dairy Division long ago devised a score card system of dairy inspection whereby the dairy farms and city milk plants are rated mathematically on a score card which comprises the desirable sanitary features in milk production and handling. This score card has been introduced in hun-

Can clean milk be produced from such dirty cows?

dreds of cities. They not only give the farmer a printed record of desirable conditions but point out where his dairy is deficient. They also serve as a guide to inspectors and limit personal opinion and prejudice so far as is possible.

The workers of the Department have always been available to city and State health departments, so far as funds permit, without cost to those helped. At the request of city officials, from one to five men have been sent to go over the situation with local inspectors and health authorities. Specialists examine the existing laws to see if they are clear and comprehensive. They then make a study of local dairy conditions, going out with the local dairy inspectors and teaching them proper methods of inspection and instruction. Attention is also paid to the laboratory control of milk supplies. The Division has been in position to render service in the standardization of laboratory methods and technic. After conditions have been thoroughly noted, meetings are usually held with farmers, consumers, physicians, women's clubs, and citizens' organizations for the purpose of explaining how local conditions can be improved and the importance of such improvement. Since inauguration of this service over 200 cities have been given the benefit of such assistance. Within recent years twenty-four complete surveys have been made in which practically every dairy farm, milk plant, and transportation agency, has been thoroughly studied. After these surveys and inspection trips, city officials are given a complete report covering local conditions, together with recommendations for changes in ordinances and methods of inspection.

It is interesting to note in connection with this work of dairy sanitation that during the war the Department cooperated with the U. S. Public Health Service in improving the milk supplies of sixteen army cantonment zones. So far as I have been able to discover, there was not a single outbreak of disease traceable to milk at any of these cantonments.

The research laboratories of the Dairy Division have been instrumental in furnishing information on which its field work has been done. Aside from the vast amount of work done by the laboratories concerning the essential factors in clean milk production and proper pasteurization, there has been a considerable amount of work dealing with laboratory control of milk supplies. For instance, the Division's laboratories have care-

A corner of one of the United States Dairy Division's Research Laboratories.

fully studied different types of media for use in counting bacteria in milk. Composition of media, their reaction, and incubating temperatures have been carefully studied and several new types of media have been evolved. Besides securing media which will give the best results for straight numerical counts, the laboratories have been successful in perfecting a number of media for differential counts. One of the interesting features of this work with media has been the adjustment on the basis of hydrogen-ion concentration. This has resulted not only in a more uniform media but it has enabled us to make certain differential media which point out differences in types of bacteria not heretofore obtainable. Specialists have only recently worked out a new media which it is hoped will give not only quantitative but qualitative counts at the same time.

Research workers in the laboratories have made extensive studies of the colon bacillus and streptococci. Results have been published on the differentiation of types, their significance in milk, and their thermal death point. These studies have had a most profound bearing on public health. The differentiation has led to a knowledge of the source of the various types found in milk and this has been interpreted to show their significance from a pathogenic standpoint. Experiments on the thermal death point of these organisms have also been exceedingly useful in determining an optimum time and temperature for pasteurization.

Hundreds of cities and towns, through correspondence and personal visits, have been led to improve their milk supplies to a great degree. Dairy laws and systems of inspection have become much more uniform and dairy farmers are accepting sane dairy inspection in good spirit. Statistics prove that farm conditions have improved and anyone familiar with the dairy business can easily see the difference between the dairies of today and those of his youth. Milk dealers' plants in the city have been equipped with better types of machinery, and approved pasteurizing devices.

The improvement seen in market milk is much more extraordinary when we realize that milk used in the average city comes from greater distances and travels through more complex channels than it did years ago. These complexities naturally add to the care which must be exercised in handling milk. In spite of this, the purity of the milk supply has not only held its own but has improved materially. A new type of man has sprung up in the dairy business; young men from the agricultural colleges, men who have been educated to the necessity of sanitary practices. The type of dairy inspectors has also changed, and cities throughout the country have much better milk supervision and a much better personnel of inspection forces than formerly. While the Department of Agriculture does not claim credit for all of the good work done, there is no doubt that its persistent efforts have had a decided influence on the situation.

# Social and Economic Aspects of Epilepsy

## Colonization Is Best Method from Viewpoint of State and Epileptic

BY DWIGHT J. LADD, CHAMPAIGN, ILL.

IT IS conservatively estimated that the ratio of epileptics to the general population is one to five hundred. At this rate, the number of epileptics in the United States would be about two hundred thousand; the number in the state of Illinois, approximately ten thousand.

There is a diversity of factors causing epilepsy. Diseases such as scarlatina, typhoid fever, measles, and smallpox may produce conditions which favor the development of epilepsy; injuries to the head or central nervous system may be followed by epilepsy; inheritance plays an important rôle. Although many leading biologists hesitate to apply the Mendelian law directly to epilepsy, they are agreed that the disease is very prone to develop in families which present a long line of alcoholic, feeble-minded, insane, and syphilitic ancestors. Epilepsy is more apt to develop before or during the age of adolescence. In a study of 460 cases made by Osler, 428 or over 90 per cent of the cases developed before the age of 15. Sex has but little influence until the age of twenty, after which time males are more susceptible to the disease than females on account of their greater tendency to become alcoholic and to acquire syphilis as well as their greater tendency to engage in hazardous occupations.

The epileptic is at a disadvantage which no other class of defectives suffers. The epileptic child of five or six years of age has normal instincts. He has the same desire for play, the same craving for love and sympathy as his more fortunate playmates who scorn and deride him because he has "fits." When he attends public school, he is seldom understood by either his teacher or his schoolmates. At recess when he should be playing with the other children, he is likely to be seeking a quiet corner of the playground. If less fortunate, he may be constantly reminded that he is different from his associates. After school he must hurry home, for his parents fear to have him away from them unless they know that he is under the care of someone to protect him from injury.

About the age of adolescence the

*The epileptic has always been under a severe handicap. As a child he is kept close at home and is thought "queer" by his schoolmates. When he attains manhood he is unable to hold a steady job for his liability to attacks makes him an unsafe risk industrially.*

*In former days the epileptic was housed with the insane, the criminal, and the County's poor. Colonization seems today the best method. In a colony, outdoor work with a minimum of fatigue is supplied to the epileptic; he becomes a unit in the organization and overcomes the embarrassment of feeling himself a misfit. By suppressing propagation, colonization is of benefit to the State.*

condition of the epileptic becomes even more pathetic. For the serious cases, school soon becomes too great a burden. Their physical development suffers little; their mental and moral faculties undergo deterioration. Their sexual passions become rampant, often making them a constant source of anxiety to their relatives and friends.

The histories of severe cases are tragedies. The following instances are typical of the social menace of unprotected epileptics:

Arthur J., sixteen years old, well developed physically, but not wanted at school, is unwilling to work. He spends his time with bad associates or ogling the little girls of the neighborhood. His widowed mother has paid out all her earnings for patent medicines and to "herb doctors" that guarantee a cure for epilepsy.

Elizabeth C. had her first spasm at the age of six, but attended school until she was twelve. At puberty she began to wander from home to become the victim of men on the streets. She was sent to the county hospital where she improved under treatment. She was released and remained at home for a time. She soon resumed her old habits and seemed to have lost all sense of morality. She gave birth to two illegitimate children, was arrested, and sent to the State Insane Asylum where she was reported to have syphilis. She is now a permanent charge of the State.

The individual, unable either to acquire an education or to hold a permanent position, is a financial loss to the State. The inability to obtain the ethical and spiritual training of the church and the school often causes many of these unfortunates to become problems for the physician, the police magistrate, and the lawyer.

The milder cases reach manhood or womanhood with a fair degree of education. They are perhaps quite proficient at some trade. Although they may have only two or three attacks during a year, the stigma of epilepsy is always associated with them. Managers of industries do not wish to employ individuals who have unconscious attacks and are likely to be seriously injured or killed as a result. Hot pipes, steep stairways, trucks and wagons are ever present, and should a person meet with an accident during an attack while at work, the employer would be liable for damages. The teaching or profession and business houses find them too great a responsibility. They go about from one position to another, seldom staying in one place longer than the first attack. In fact, the only work open to them are odd jobs and such positions as sympathetic employers may give them. It takes but a short time spent in wanderings of this kind to make the epileptic lose all hope of ever being of any use in the world. They realize that they "just exist"; they are ready for death; they often welcome it.

Under such circumstances both the epileptic and the family suffer. He must either "eke out" a meager existence with improper care or the living conditions of the family must be lowered. In the one instance, the epileptic remains a menace; in the other the family suffers an injustice: in both the State is injured because of its inefficient members.

It is not by a cultivation of a "higher" type of people, but by a more general conformity to a standard that society progresses. As the land of the State could by scientific cultivation be made to increase its yield, so could the people be brought to realize more of the values of life if they were able to attain more general

conformity to the present level of effectiveness. One would not expect to receive a hearty welcome of such improvements as community playgrounds, better schools, or better housing among a population reared in the dregs of human misery. As the individuals of a society prosper, the State progresses. It is the defective at large, who by his promiscuous habits swells the number of dependents and undermines the welfare of the State.

The rather recent places for treatment of epileptics were the county poor houses. This was doubly unfortunate. In the first place, it was unfair to the other inmates. As no provision was made for the distinction of cases, the epileptic, the vagabond, the "dead beat," and the unfortunate who had worked all of his life were thrown together. They were compelled to witness scenes which made them feel their misfortunes more keenly. It was also unfair to the epileptic to be detained in the poorhouse as he came to be regarded as "worthless." Grudgingly he was given charity when what he needed and craved was merely a chance to cultivate his own abilities under competent supervision.

#### Colonization Best Method

The practice of keeping epileptics in the insane asylums was worse than "poor house imprisonment." The horror of such treatment cannot be adequately described. It did not take many months of association with the insane to make the epileptic worse or insane. That such conditions were tolerated as long as they were is incredulous. Nevertheless, it was not until the middle of the nineteenth century that steps were taken to provide adequate care of epileptics. In 1867 a colony for epileptics was founded at Bielefeld, Germany. In the colony, the epileptic was associated with others similarly afflicted. He lived through the same trials and cares as those about him did. A bond of sympathy sprung up between the inmates. They understood and helped one another. It was also possible to make group studies of epileptics and work out a definite plan of colony care. A few years later colonies were built in England. In 1890 Ohio became the first state to establish an epileptic colony. Others were organized in New York (1894); Massachusetts (1898); New Jersey (1898); Kansas and Texas (1902); Indiana (1905); and in Virginia and in Connecticut (1910). Both Michigan and Minnesota have now provided institutional care for epileptics. The largest

institution of this kind in the United States is the Craig Colony for Epileptics at Sonyea, New York. The daily average population for the year 1912 was 1381. The net cost to the State for the year was \$234,224.02, the cost per patient being \$169.59.

A colony should be located on wooded, slightly rolling land. This affords a natural means for segregation of the inmates. Each colony should have two main divisions, one for men and one for women. In each division, separate provision should be made for different grades of mentality. Separation by natural means such as woods or hills tends to make the patients more contented by removing the appearance of mechanical restraints. Buildings should be low one story structures of the bungalow type. Steep stairways and sharp corners should be avoided in order to decrease the danger of injury during an attack. Single rooms should not be used. Wards which can accommodate about twenty-five of the brighter patients should be provided; the lower grades can well live together in groups of about sixty.

Epileptics progress best when kept busy enough to produce a normal fatigue without over-work. The kind of work best suited for this purpose are outdoor occupations, such as gardening, carpentering, and blacksmithing. Manual work indoors is also helpful. No duty should be assigned which would endanger the life of a patient should he have a seizure. Tranquility in all undertakings is essential to his welfare. Outdoor recreations such as baseball, tennis, and skating should be provided. Socials, parties, and dances may be held for the milder types of patients. In fact, a quiet, normal routine of life is essential to the well-being of the epileptic.

#### Control of Propagation

A patient should prepare to remain in a colony indefinitely. This is not such a hardship as it would seem. A colony of epileptics is indeed a village in itself. Here the epileptic is among those of his own kind. He is a unit in the organization, not an unwelcome spectator. Life is again worth the living and he is a "man for a' that." Colonization helps to check the number of epileptics through suppression of marriage. Heredity plays an important part in epilepsy; some authorities place the number as high as 75 per cent. Control of propagation in this manner may seem a hardship, but to one who can look ahead and see the defective child, the misery

and suffering it is going to cause, the advisability of such a régime will at once become apparent.

The epileptic is the cause of one of our urgent social problems. Our society has no place for him, he is friendless, too often homeless, and after continued discouragement, is hopeless. The colony is the only satisfactory method of treatment. It is only through systematic care that the epileptic can be made even partially self-supporting. It is not only better for the patient, but cheaper for the State. The per capita cost is less. The colony treatment, and only the colony treatment, furnishes a means whereby eugenic principles can be applied to weed out the defectives from society, a society which needs for its continuance the individuals best endowed physically and mentally.

#### National Conference of Social Work

Progress in social affairs, trends indicating the channels of activity in the next year, and arguments unanswerable demanding organized effort for human betterment are all brought out in the topics announced for the Forty-ninth Annual Meeting of the National Conference of Social Work, to be held at Providence, R. I., June 22 to 29, 1922.

Among the announced titles the following are significant:

Neglected fundamentals in children's work; underlying concepts in the world movement for health; the future of a community in an industrial civilization; racial diversities and social development; health experiments and demonstrations; the art of living; minimum standards of training for family case work; social standards for industry; community organization; rural communities; mental hygiene as a vital factor in education; mental hygiene in childhood; functions of the public and private agencies in the welfare work of the future; public welfare departments, their scope and form; and international aspects of the immigration problems.

The speakers on the program include the following: Allen T. Burns, Fred Croxton, John B. Dawson, Dr. Neva Deardorf, Prof. Julius Drachler, Dr. C. E. Ford, Dr. C. Floyd Haviland, Robert W. Kelso, Prof. E. C. Lindemann, Dr. Charles S. Little, Owen R. Lovejoy, J. Prentice Murphy, Dr. C. C. Pierce, George Soule, Dr. Russell D. Sprague, Dr. Douglas Thom, Dr. George E. Vincent, and Dr. William A. White.

# The Care of the Foot During Childhood

BY JACOB GROSSMAN, M.D., JUNIOR ADJUNCT ORTHOPEDIC SURGEON, LEBANON HOSPITAL; CHIEF OF THE ORTHOPEDIC CLINIC, LEBANON HOSPITAL; CHIEF OF THE ORTHOPEDIC CLINIC, STUYVESANT POLYCLINIC, NEW YORK CITY

THE importance of the routine examination of feet in children is at last being recognized. Heretofore, the eyes, the ears, the lungs, the teeth and hearts of children were all carefully examined. Very little attention had been given to the condition of the feet. Recognizing this lack of proper attention to a very important subject, the writer has published several articles in which stress was placed on the importance of including foot examinations in the general routine physical tests applied to children.

The first of these articles was entitled "Weak Feet in Children" and was published in the *Medical Record*, June 8, 1918. The second manuscript was entitled "A Plea for More Active Treatment of Weak Feet in Children" and appeared in the *Western Medical Times*, March, 1921. The final manuscript was entitled "The Value of Pedographs in Recording and Diagnosing Abnormal Foot Conditions in Children," and was published in the *Medical Record*, April 23, 1921. The present contribution will combine the main features of the three preceding manuscripts plus new observations noted since their publication.

From a clinical viewpoint weak feet in children do not differ materially from those in adults; still the history and the symptoms in the former are so different from those in the latter that a special description of the condition is warranted. Search of the literature reveals that until recently, this very important ailment in children had been very little emphasized. Many children are permitted to go through childhood handicapped by weak feet which in the majority of instances would respond to very simple corrective measures. After a very careful observation of an extensive number of cases of weak feet in adults, there is no doubt in the mind of the writer that in the vast majority the predisposition to weak feet or weak feet can be traced back to childhood. In other words, had better care been given to the feet of these patients when they were children, needless suffering in later life could have been avoided.

In the offspring of parents in whom there is a history of weak feet I have not infrequently found existing weak

feet or a predisposition toward them. It is not uncommon to find a mother bringing to the clinic several children, all having weak feet. This fact with the many instances of familial weak feet that I have encountered in the clinics suggests that possibility of an inherited predisposition in those cases.

In infancy and early childhood the feet appear to be flat; this flatness is not permanent, but is the result of the osseous structures of the arch being surrounded by pads of fat. This has been proved by examination of frozen sections of specimens. As the child develops, the fat gradually disappears and the arch becomes more conspicuous. This change usually be-

Henrietta V., two and one-half years of age. Marked congenital weak feet.

gins in the second year of life and is completed after the third year.

Normal children, when left to themselves, usually begin to creep during the seventh and eighth months. This should by all means be encouraged, as it meets the natural requirements and trains the bones, joints, and muscles to bear weight. After this creeping period comes a more trying period, that of walking. The transition from the former to the latter should be a natural one. When children are taught to stand on their feet too early, the untrained muscles, bones, and ligaments yield to the over-

weight; deformities of the foot are produced that may lead to the marked degree of deformity which we see in weak feet. The weight forces the astragalus forward and downward upon the oblique articulating surface of the os calcis, at the same time calling forth an outward rotation of the astragalus. This intended torsion is communicated to the other bones, resulting in a turning outward of the foot. The inner border of the astragalus endures more weight, the os calcis is turned outward, and a weak foot is the result. Hence it is safest to permit children to begin to walk when they themselves so desire. Premature walking aided by artificial appliances or devices is harmful and unnatural and should therefore be avoided.

Weak feet occur more frequently in females than in males. It is quite a common condition before the thirteenth year. The condition may be congenital or acquired. Congenital weak feet are occasionally found in combination with club feet. There is a tendency to weak foot deformity in a certain percentage of newborn infants. A marked flat-foot deformity is not of frequent occurrence. The dorsum of the foot during the embryonic stage is pressed against the leg and retained in that position after birth. The feet of the newborn persist in this attitude of rest for a long time. This should not be mistaken for a pathological condition. As time elapses the position of the feet in the majority of instances assumes the normal relationship to the legs. In instances where this attitude of the feet persists for a long time, can the feet be considered to be congenital weak feet? In some of these cases the sole of the foot is flat; in others it is convex. The contours of the bones are visible under the skin. The peroneal, flexor, and dorsal muscles of the foot are shortened.

Predisposition to weak feet due to heritage must again be emphasized. Many cases of weak feet in the offspring are found to be present where one or both parents have the condition. I have been strongly impressed with the frequency with which I have been able to demonstrate weak feet in brothers and sisters, as well as in one or both parents.

Acquired weak feet may be the result of, or occur in conjunction with, many conditions. In children with a general muscular relaxation, weak feet are very often present, the result of muscular weakness. Infantile paralysis in which the tibialis anticus is involved is the cause of paralytic weak feet. Rickets, especially with genu valgum, is often accompanied by weak feet. Injuries, among which fractures are the main ones, often give rise to traumatic weak feet. Occasionally the injury is the result of a wagon wheel passing over the foot, or the falling of a weight upon the foot. Overweight is a common cause of weak feet. Prolonged rest in bed from any of the infectious diseases, inflammatory or infectious conditions in or around the ankle or foot, may predispose the individual to weak feet. It is true that in a number of instances the history of the predisposing or exciting factor cannot be ascertained. It is a difficult matter to determine the cause in these cases.

#### Shoes in Causation

Poorly fitting shoes in children can in the majority of cases be eliminated as a causative factor in the production of weak feet. The shoes made for children are very good ones; they have broad toes and are roomy enough to permit of free action of the small muscles of the feet. It is very important to wear stockings that fit well. Stockings which are too tight or too small will cramp the foot and in that way interfere with the proper action of the muscles of the foot, thereby predisposing the child to weak feet.

In the average case the foot appears to be turned outward below the

What weak feet can do to shoes.

ankle and the axis of the lower leg presents an outward deviation in the plane of the ankle. The internal ankle may project from a slight to a considerable degree. The arch of the foot is not only lowered, but in severe cases appears to be convex, the bulging resulting from constant lowering and outward turning of the head of astragalus and scaphoid. The inner border of the foot appears to be much longer than the outer.

In those cases resulting from a specific cause, such as infantile paralysis, injury, an infectious process, etc., this history is elicited. Some children have a limp, some fall, others turn the ankle; in other instances the children walk with the toes pointing outward. There are other instances where there are no subjective symptoms. The children are brought to the clinic because they always wear their shoes out on the inner borders of the soles and heels. In these cases the shoes are not only worn out on the inner borders of the soles and heels, but the inner surface of the last of the shoe is distinctly prominent and bulging, the result of the constant pressure of the displaced astragalus and scaphoid. Occasionally the children will complain of pain in one or both legs, the location of which pain is variable.

At times it may be referred to the inner border of the boot, but more often it is referred to the calves of the legs. Other children tire easily and want to be carried continually. These children are often punished for refusing to walk as their parents feel that they are lazy and "spoiled" and therefore refuse to walk. There is not a child who is normal in every way, who would refuse to run and jump if permitted to do so. When they refuse, the only logical reason is that there is something the matter with them.

#### Symptoms of Weak Feet

In a number of instances the children are brought to the clinic to be treated for a sprain or a fracture of the ankle and the presence of weak feet is discovered for the first time. In these cases the history of any of the aforementioned subjective symptoms cannot be elicited. The mothers are unaware of the fact that their children have weak feet.

The gait of children who have weak feet is awkward. They walk upon the entire sole of the foot. The toes turn out and the soles and heels are worn out on the inner borders. The most important objective symptom is the eversion of the heels and heel cords. In the normal foot the heels and heel cords are either parallel to, or converge slightly toward a line drawn perpendicularly through the center of the trunk and continued downward to the ground. In weak feet there is a tendency for the heels and heel cords to be everted, to roll away from this midline. The eversion varies. In mild cases it usually is very slight, while in the more severe cases it may be very marked.

Accompanying the eversion there usually is a lowering of the arch as a whole. In the early cases disturbance in the osseous structure of the arch is not discernible; there may be, however, a slight stretching of the ligamentous and muscular structures. As the condition progresses, the ligaments and muscles become more and

Edward B., eighteen months of age. Congenital weak feet.

Dora B., ten years of age. Her chief complaint is pain in the knees and calves. She shows second degree weak feet.

more stretched until finally there is complete collapse of the keystone of the arch and the sole of the foot becomes applied to the ground, resulting in a pes planus. With these changes the eversion of the heels and heel cords keeps pace, so that marked eversion is always present in the advanced cases.

#### Aids to Diagnosis

The displacement of the anterior tibial line is another valuable aid in diagnosing weak feet. Normally, the anterior tibial line falls over the first or second toes; in weak feet it usually falls towards the inner side of the big toe or over the center of the inner border of the foot. The anterior tibial line is found by following a line passing along the crest of the tibia and continuing it along the dorsum of the foot.

Spastic or rigid weak feet are rare in children. Occasionally one may be encountered. In these cases there is limitation of the range of motion due to the spasm of the muscles on the dorsum and outer side of the foot; the spasm resulting from shortening and contraction of these muscles owing to the persistent attitude of valgus.

The diagnosis of weak feet in children is made in the majority of instances by inspection. Occasionally walking or hopping tests may be used in addition. These methods are sufficient to give one a mental picture, which for the time being may enable one to make the diagnosis. We have no means at the present time of comparing these findings with those pre-

sented six months later, should our advice as to the improvement of the patient's condition, be sought for. We cannot say with any degree of accuracy whether the patient's condition has improved, remained stationary or become worse. By means of properly made pedographs, we have a photographic reproduction of the condition of the patient from the initial visit, with which subsequent pedographs, taken at any subsequent time, can be compared. Hence we have at our disposal a means whereby we can accurately tell the patient what has occurred as the result of our treatment.

By the pedograph method five prominent signs are taken into consideration: (1) the pedograph picture; (2) the contour line; (3) the distance of the keystone of the arch below the Feiss line; (4) the muscular development of the soles of the foot, especially those under the arch of the foot; and (5) the presence or absence of the juvenile fat pad.

In taking the imprint the child places one foot in a solution of iron. The foot is then placed upon a blotting paper and the child is told to place all the weight on that foot. At this point the contour line is drawn by using a pencil held at right angles to the plane surface. This contour line demonstrates the degree of eversion of the heels and heel cords and the degree of inversion of the ankle. The muscular development of the soles of the feet should then be taken into consideration, as often a heavy bulging muscular layer will produce a picture of inversion of the

ankle. The foot is then removed from the blotter and the distance of the scaphoid below the Feiss line is estimated. The Feiss line is represented by a line drawn from the posterior inferior aspect of the internal malleolus to the first metatarsophalangeal joint on its planter aspect. The scaphoid in the normal adult foot is usually found to be one-half inch below this line. In children it varies with age. The sole of the foot is then palpated and the muscular development noted as poor, fair or good. The presence of the juvenile fat pad is also sought for.

A solution of tannic acid is now applied to the iron imprint, which turns a jet black, giving us a record which can be preserved indefinitely.

The base lines and the auxiliary lines are now drawn on the pedograph for the estimation of the deformity should one be present. The first base line is drawn from a point posterior to the internal malleolus to the first metatarsophalangeal joint. The contour line extending beyond this denotes the degree of inversion of the ankle or eversion of the heels and heel cords. The line of axis weight bearing is next drawn, from the center of the heel to a point midway between the first and second toes. A line is next drawn at right angles to the line of axis weight bearing from a point posterior to the heel. Another line is drawn also at right angles to the line of axis weight bearing, from the first metatarsophalangeal joint. Midway between the last two lines, also at right angles to the line of axis weight bearing, is drawn the line of estimation. The line of estimation is then checked. One check is placed at the outer border of the imprint, the other check being placed at the junction of the line of estimation and the first base line, or should valgus be present, at the junction of the line of estimation and the contour line. Midway between the two check marks of the line of estimation is the normal point. To the inner side of this point the line is divided into three parts, each part representing one degree of weak foot, while to the outer side of the point the line is also divided into three parts, each part representing one degree of pes cavus.

The use of pedographs in diagnosing and recording weak feet is by no means new. It has been advocated by Rice of Washington and used extensively in the marine corps by Mann and Folsom. However, it has not, as far as I have been able to

learn, been used in the care of children.

With the hopes of standardizing the findings in children, one hundred who were assumed to have normal feet have been pedographed. These children were selected because they had no symptoms referable to foot disturbances. The age of the youngest child was two years and the oldest thirteen. Several were chosen in each year between these limits.

### Graphic Records of Progress

From the study of these cases the following facts have been evolved:

(1) Up to four years of age, with few exceptions, the pedograph picture is of no value, as the juvenile fat pad, which is invariably present, always gives a flat impression similar to that present in the third degree weak foot. This flat impression does not represent any pathological change, as it is not due to a flattening of the bony arch. This has been proven by frozen sections of the foot, which have demonstrated that the bony arch is normal and the hollow of it is filled by a pad of fat. However the distance of the scaphoid below the Feiss line, the condition of the musculature and the fat can be determined in these cases. The average distance below the Feiss line for children of these ages was one-eighth of an inch for children two years of age and one-quarter of an inch for those three and four years of age.

(2) The average distance of the scaphoid below the Feiss line in normal children five years of age was one-quarter of an inch. For children six, seven, eight and nine years of age, it was found to be three-eighths of an inch. For children ten, eleven, twelve and thirteen years of age, it was found to be one-half an inch. As a rule variations from these averages indicated abnormal feet.

(3) The muscular development was fair in nineteen and good in eighty-one. In the former cases weak feet were invariably found.

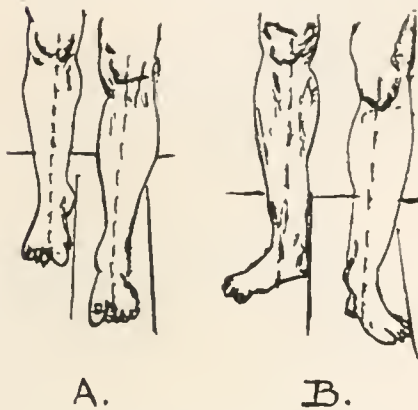

(4) The pedograph was normal bilaterally in forty-two cases and unilaterally in thirteen cases. It was abnormal bilaterally in forty-five cases, thirty-three showing weak feet and twelve showing pes cavus. Of the former eleven were apparent weak feet, the weak foot impression being due to juvenile fat pad, and twenty-two were pathological weak feet. Of the thirteen unilateral cases, nine showed weak feet and four showed pes cavus. The weak feet and the pes cavus deformities varied from one-half to three degrees. In weak feet the scaphoid was further below the Feiss line and in pes cavus it was further above than in the normal foot.

(5) The fat pad was especially marked in children up to four years of age. In many of these children it was responsible for the flat impression present.

While this method of recording and diagnosing abnormal foot conditions in children may not be infallible, yet

in it we undoubtedly have the foundation upon which we can accurately study successive changes in the foot.

A great deal can be accomplished

The anterior tibial line: (A) Normal; (B) in a case of weak foot. Displacement of this line is a valuable aid to diagnosis of weak feet.

in the prevention of weak feet. The feet of children should be examined as frequently and carefully as the eyes, teeth, heart and lungs. Where there is any suspicion of weakness or a tendency towards weakness proper measures should immediately be instituted.

The feet of small children should not be forced or pressed into shoes. The children should be given frequent opportunities to walk in their bare feet. This allows free action of the muscles and hence strengthens them. Creeping should be encouraged as much as possible. Infants should be placed upon their abdomen as soon as practicable. The desire for locomotion will soon induce children to creep and frequent opportunities will eventually accustom them to this new achievement. The creeping pe-

A good orthopedic shoe. Note the elevation on the inner border of the sole and heel.

riod should not be suppressed. Permitting the child to sit too early will encourage it to slide over the floor on its buttocks. This will delay creeping and should not be permitted.

The period of creeping should be changed by the child into one of walking. Only when a child of its own accord attempts to stand up and walk, holding to surrounding objects, should it be permitted to do so. To force them to walk prematurely, with the aid of either nurses or walking appliances is objectionable. All such devices are impracticable and unnatural. Hastening the commencement of locomotion predisposes children to weak feet.

### Prophylactic Treatment

Regardless of the presence or absence of weak feet, broad-soled sandals for the younger children and good orthopedic shoes for the older ones should always be recommended. These allow of free and unrestricted action of the toes and small muscles of the fore part of the feet.

If very young children proper sandals or shoes will usually suffice to overcome weak feet. The sandals or shoes should have broad toes, they should have a lift of an eighth or one-fourth of an inch on the inner border of the soles and heels. The thickness of the lift depends upon the weakness of the foot. The weaker the foot the thicker the lift. Laced shoes are to be preferred to those that are buttoned.

If after a reasonable length of time the shoes fail to relieve the condition braces must be added to the treatment. The brace which has proved to be very efficient is the Whitman brace. The brace is modeled upon a plaster cast of the foot taken while the foot is held in the fully corrected position. It fits the arch of the foot accurately, extending forward to the ball of the big toe, outward round the outer border of the foot and backward to just in front of the tuberosity of the os calcis. On the inner side it is enlarged upward and extends to a point one-half inch below the internal malleolus. With a properly made brace the foot should rest upon its normal bases of support, i. e., the under surfaces of the heads of the first, fourth, and fifth metatarsal bones and the tuberosity of the os calcis. These braces should be accurately fitted and each should be made for the individual who has to wear them.

The method of taking the cast of the foot which the writer has found very efficient is a very simple one. The patient sits upon a chair with his foot upon a second chair of the same height. On this chair is placed a small cushion covered with a towel

on which talcum powder has been sprinkled. Plaster of Paris is then mixed with water to form a thick cream; a piece of gauze is then steeped in the plaster of Paris cream and laid upon the towel, underneath the foot, so that the outer border of the sole rests upon it along a line about an inch from the edge. The foot rests upon its outer border and is held at a right angle to the leg. The gauze is then wrapped around the foot, covering in the heel behind and extending as far forward as the cleft between the toes; it should reach up above the internal malleolus, but should not overlap the dorsal surface to any extent. This covering is permitted to set and when the plaster is hard there is no difficulty in removing the foot from it. A fresh plaster cream is now made. The mold is well powdered and the plaster cream is poured into it and arranged so that it fills the mold, but does not project beyond it in any direction. When the plaster has set the sides of the mold are forced aside, the cast is removed and properly carved for the instrument maker.

The brace is made of thin steel or aluminum alloy and should extend forward to the line of the metatarsophalangeal joint of the great toe and backward to the center of the heel; on the outer side it grasps the foot just behind the prominence formed by the fifth metatarsal bone and on the inner side of the foot it extends upward to one-half inch below the internal malleolus. It should fit the cast accurately, except over the heel, where it should be slightly flattened so as to make it steadier. It should be worn for short periods at first, the length of time being gradually lengthened as tolerance is established. The length of time the support is necessary varies with the condition of the patient and the strain to which the feet are subjected. The brace should be corrected from time to time so as to conform with the changes taking place under its use.

In older children we have slightly different conditions with which to contend. Pain, rarely present in the younger children, is one of the common complaints of the older ones. For the acute pain strapping offers the quickest relief. One end of a strip of adhesive plaster about seven inches long and one inch wide is applied to the outer side of the ankle just below the external malleolus; the foot is then adducted as far as possible and the plaster drawn tightly beneath the sole up the inner side of the arch and the leg, being

kept in this position by one or two strips about the calf. Strips about half an inch wide are then applied in a figure-of-eight manner about the arch and ankle, beginning at the back of the heel and extending as far forward as the base of the first metatarsal bone. Strapping should be done twice a week and continued until the pain has subsided. Where necessary, shoes and braces should be recommended.

#### Corrective Exercise

When children are old enough exercises have proved valuable adjuncts in obtaining a successful issue. The following exercises have been found to be very efficient:

(1) Tip-toe exercises: the patient places the limbs in the attitude of moderate inward rotation, raises the body on the toes to the extreme limit, the limbs being fully extended at the knees, then sinking slowly, resting the weight on the outer borders of the feet in marked varus, repeating about twenty to thirty times.

(2) Walking in bare feet is very beneficial and should be instituted as soon as the child begins to walk.

(3) Walking on the forepart of the foot.

(4) Grasping motions with the toes combined with exercises with foot weights or marbles are very valuable.

(5) Bicycling has also proved of value and should be highly recommended.

Exercises should be practised twice daily and should not be carried to the extent of tiring the patient.

In the younger children the exercises enumerated can be arranged in the form of games so that they will be more attractive to them.

In a number of instances operative interference is indicated. This is especially so in those cases due to infantile paralysis and congenital deformities.

If after the period of spontaneous recovery has elapsed paralysis of the tibialis anticus has not been overcome, operation may become necessary. The operations which have proved satisfactory are tendon transplantation and tendon fixation. These operative procedures are too well known to require detailed description. Suffice it to say that they should be employed where the indication exists.

Achillotomy followed by proper after measures should be resorted to in those cases in which the tendo Achillis is contracted.

Arthrodesis, removal of a wedge-shaped portion of the tarsus, bone grafts have all been advocated. Fortunately these operative procedures are not commonly required.

## Physical Education Association

BY DUDLEY B. REED, M.D., PRESIDENT, AMERICAN PHYSICAL EDUCATION ASSOCIATION, CHICAGO

THE twenty-ninth annual convention of the American Physical Education association was held in Detroit, May 3, 4, 5 and 6, 1922. In point of attendance it was the largest in the history of the association, eight hundred and ten delegates being registered.

The general theme of the meetings was "The Objectives of Physical Education" and the speakers included a number of well known general educators. Among these was Professor Kilpatrick of Teachers' College, Columbia University, who gave a very stimulating address on the subject "Is Physical Wellbeing the Sole Object of Physical Education?" He pointed out the fact that no educational activity has one result only, giving as an illustration the case of a boy to whom is given the task of learning a poem. He indicated that the memorizing of the poem is far from being the only result of this effort. It also affects the

boy's attitude toward poetry in general, his attitude toward school, toward study, toward his teacher, toward authority, and toward society. Moreover, the boy's habits are influenced, his habits of posture and his habits of study among others. Similarly in the activities of physical education, whether we will or no, we shall obtain many results other than the gaining of skill and strength in the particular exercise which is being done, results in habits, attitudes and character. The objectives of physical education should be largely governed by the results which may be attained. Therefore his conclusion was that health is an important objective, but far from the only objective of this branch of education.

Professor Clark W. Hetherington, also of Columbia, made the point that no educator should consider that he is teaching a subject to a child but rather that he is educating the child.

Physical skill, strength and organic vigor are important aims in physical education, but other aims are social and moral qualities which make people better citizens and more useful members of society. These two speakers and Mr. Courtis, the director of public instruction of Michigan, all stressed the importance of cooperation among the different departments.

Throughout the meetings the gen-

eral feeling was that the physical educator has an exceptional opportunity in promoting health and the other results to be gained by his work on account of the fact that he is supervising children along the lines of their natural interests. He should cooperate to the fullest extent with other agencies striving to promote health. A part of the demonstration of activities by the Detroit school children was an interesting health play.

Those who are engaged in athletic work for girls and women held a session for three hours on Saturday morning and were unanimous in the opinion that girls should not be exploited for purposes of athletic exhibition; that athletics should emphasize participation by all who are physically fit rather than public competition by the most skillful. They were opposed to intercollegiate and interscholastic competitions for girls.

## Wins Against Mental Disease

**I**NSANITY has been robbed of many of its terrors. It may be conquered if attacked during its incipient stages. Even the more advanced cases may be arrested if vigorous effective measures are adopted. How this has been demonstrated at the Trenton State Hospital, where epoch making recoveries of insane patients are reported, constitutes the message from Burdette G. Lewis in the April issue of the *Review of Reviews*. As a result of the treatment provided during the last three years one thousand patients in the so-called "incurable" group have been discharged. The discharged rate for the "functional" group has averaged 65 to 70 per cent of the admissions for three years, as against a ten year average of only 37 per cent.

Dr. Henry A. Cotton, medical director of the Trenton State Hospital, in 1918 surprised the medical profession by stating that the extraction of infected teeth, the removal of infected tonsils, and the clearing up of infection in the stomach, duodenum, the lower intestine, and in other vital parts of the bodies of insane patients had resulted in remarkable and unanticipated recoveries. The consistent effort to clear up focal infections of this kind by Dr. John W. Draper, attending surgeon, has achieved results in insane patients which are striking and sensational. The application of all the well tested methods of modern medicine, surgery, and dentistry has penetrated the mystery which has enshrouded the subject of insanity for centuries, and has opened up the way for fundamental changes in the hospital management of insane patients. Typical cases are reported in which after no more radical treatment than the extraction of badly infected teeth has restored supposedly incurably insane patients to mental health and to industrial productivity.

The humane side of the subject can

well be appreciated for it connotes the replacement of traditional dungeons or strong rooms and burly keepers with hospital surroundings, nurses, sunlight from expansive windows, and an environment that soothes and quiets the patients. Proper segregation and early treatment mean early recoveries. Removing the terror and torment that afflict the insane patient helps to accomplish the desired result. The newer methods have served to reduce the average stay of recoverable patients in the hospital from nine

all hospitals for the insane throughout the country, continue, to their own shame and to the detriment of the patients, to employ mechanical restraint. There is no necessity for it, as the writer can testify from his own experience. When he took over the State Hospital at Trenton, he found over ninety women in strait-jackets, and all other forms of restraint were in daily use. In less than two months over seven hundred pieces of restraint apparatus were removed from the wards, and since that time no patient has been put in restraint for any cause.

The work at Trenton has found

The modern room for receiving psychopathic patients at the Trenton, N. J., State Hospital differs in no way from the diagnostic clinic of any other general hospital. It has the advantage of correcting early such physical defects as may cause or aggravate the condition. A mental quirk has a much better chance of being straightened out if the physiologic functions are put in order first.

to three months, and incidentally have made possible an economy to the state that is not to be despised.

All restraining apparatus has been eliminated at the Trenton Hospital, as it has been found unnecessary in handling either new arrivals or the chronic patients. On this subject Mr. Lewis quotes Dr. Cotton as saying:

Even today, at least 80 per cent of

striking confirmation in Illinois. The results obtained when shackles are removed are, according to Charles W. Thorn, of Illinois, a challenge to every old fashioned hospital administrator in the land.

Two new buildings dedicated to preventive treatment were recently opened at Trenton. Hereafter, alienation is regarded as a symptom, and

every committed person will hereafter be regarded as a patient who is entitled to receive the most complete and expert diagnosis and treatment, corrective and remedial in the effort to remove even remote conditions con-

fusion, and misery beyond words. There were actually fifty-five fewer non-paying patients in the Hospital July 1, 1921, than on July 1, 1918 alone effecting a saving of \$116,000 in maintenance charges the past year.

Where accuracy triumphs over guesswork. Where accurate study is made of each disease picture presented, precise methods become impossible. The procedure in this case is the administration of salvarsanized serum through an opening in the skull.

tributing to the mental upset. Particularly interesting and far reaching in its effects is the research directed toward the ductless glands. Some of these studies have led Dr. Cotton and his associates to the conclusion that bacterial infection of these glands is more serious in its effects in causing the under development or improper functioning of these glands than is commonly supposed. Some of these viewpoints are fundamental in the consideration of mental disorders. The belief that the disorders of these mental patients are fundamentally a disease of the mind, rather than physiologic disturbance of the vital organs, including the brain, has delayed physical treatment and has seriously retarded progress in this group of diseases.

Cities and states throughout the Nation which are contemplating the expenditure of millions for custodial asylums need to consider the matter of diagnostic and medical survey of committed patients in its bearing upon the economic and humanitarian handling of these subjects. New Jersey's experience has made the old fashioned asylums, camouflaged as hospitals, as extinct and out of date as are the prison grottos of old Venice, or the Bethlehem hospital for the Insane in England, known as "Bedlam" which was so notorious that the word "bedlam" now signifies fury,

Moreover, voluntary patients have paid more than \$50,000 for treatment during the same period. Taxpayers should be brought to realize that they pay the staggering sum of ten thousand dollars for each indigent case committed for life. Under the old system two-thirds of all commitments are for life, and insanity has quadrupled while the general population has doubled! In New Jersey alone an extension of the extraordinary results herein reported would mean that there will be no necessity of building an addition each three years to care for 324 additional custodial patients "in for life," and that a large part of the old asylum section of the Trenton Hospital, upon which more than two million dollars had been spent in recent years, can be abandoned before long or converted to other uses.

### Health Week Announced for October

The week of October 23 to 30 has been set apart as "Health Week," with the suggestion that emphasis be placed on ventilation, sanitation, and personal hygiene. It is significant that improvement in health conditions has been effective on just the points where the attention has been focused and in the degree that personal and community responsibility has been assumed. Health week is set at an op-

portune time, when especial attention is necessary to provide healthful indoor conditions.

Many "weeks" devoted to one cause or another have resulted in tremendous activation in these several fields. When universities and colleges found themselves obliged greatly to increase their funds or reduce standards they put their case up to the people in educational drives that resulted not only in financial stability for these organizations, but found their best expression in an enlightened public inquiry into educational methods of the most far reaching importance. Thrift week put unprecedented sums of money in the banks, instituted many systematic investments, and excited an unprecedented interest in the underlying causes for economic stress. It stabilized the sense of personal responsibility.

It is interesting to speculate on the possibilities of "Health Week" properly organized and sufficiently backed by popular interest. That health is an asset really calls for no argumentation. Everyone desires health for himself and regards it as a blessing when it is bestowed upon him. The chief difficulty is that health is popularly regarded as a gift, not as an achievement. Supine, lackadaisical acceptance of conditions conducive to ill health and inefficiency are quickly dissipated when health facts are properly presented. With the present state of sanitary science there is no excuse for the popular notion that sickness "happens." Sickness and inefficiency are not chance products any more than health is a "gift." The laws of cause and effect apply, and it is up to an enlightened public to understand and provide the physical conditions productive of public health.

Physiological righteousness is the price of health. Personal hygiene, a definite application of the laws of dietary knowledge, the opening of our windows, cleaning up our backyards, straightening out defective plumbing, removing poisonous gases in industrial plants, care as to water supplies and sewage disposal, rational ventilation in the home, personal hygienic practice—all are proper subjects for emphasis in "Health Week." If health workers seize the opportunity to organize and popularize some of the more recent findings of research workers on ventilation, on the sanitation of the home, and of the cooperation necessary from the individual to maintain community as well as personal health, the observance of "Health Week" should result in a better popular support for a rational public health program.

# Acute Infectious Diseases in New York City

## Two Decades of Inspection from the Standpoint of the Medical Inspector

BY JOHN RANDOLPH GRAHAM, M.D., BOROUGH DIAGNOSTICIAN, BUREAU PREVENTABLE DISEASES, DEPARTMENT OF HEALTH, NEW YORK CITY.

THE doctor in the Health Department is sometimes asked this question, "What possible attraction is there in your work which can induce a physician with a reasonable amount of ambition to devote to it a good share of the best years of his life?" Speaking from the point of view of one who for a great many years has been engaged in the inspection and diagnosis of acute infectious diseases, it can be answered that, aside from the material benefits which may accrue to the inspector as a result of his labor, the Department of Health offers the man for whom infectious diseases in general and the eruptive diseases in particular hold a fascination a service always rich in opportunity, a wealth of material, and an experience which seldom grows stale. True it is, the doing of this work involves at times both annoyances and hardship, but such things are more than counterbalanced by the compelling interest most of us feel in the wonderful variety of things we are forever doing and seeing and in the numberless incidents, grave and gay, which befall us from time to time. Doubtless every medical inspector has gone home on more than one night calling upon all the Saints to witness that he was through, that never again would he submit to the inhuman and indecent treatment which was his daily portion, only to arise with the light of another sun and take up his stride where he left it the evening before.

### Old Time Medical Inspection

The methods of handling the acute infectious diseases in the field have undergone many modifications in the last twenty years, and in consequence the present day inspector has a decidedly happier lot than did his predecessor of the former day. In the early years of this period, the work was looked after by two varieties of the genus medical inspector, namely, the diagnostician and the district inspector. With the diagnostician of that date, this paper has little to do, and it suffices to say that he was looked upon by his more humble accomplice as a kind of medical high-

*To the medical inspector in New York City is given the opportunity not only to study an unusual variety of communicable diseases but to him is given first hand knowledge of human nature in all its moods.*

*The duties of the medical inspector of the old days who was on call at any time to calm irate citizens, enforce quarantine rules on recalcitrant tenement dwellers, and vaccinate grumbling flop house inmates are quite different from those of the present day diagnostician under whose surveillance comes a whole troop of infectious diseases, some exceedingly rare. Like the stage and the newspaper, medical inspection holds a never ending fascination for the physician thus engaged.*

brow who did most efficiently the work called for by the title he bore. On the other hand the district man was the handy man of the Department, the "hewer of wood and drawer of water," and his duties were multifarious. There came to his hand every conceivable kind of complaint originating in his district from the perfectly legitimate request that he investigate some breach of quarantine to the wherefore of the dead cat on the sidewalk. He attempted with varying degrees of success to calm down citizens who were angry as a result of some injustice or indignity which had been foisted upon them which, incidentally, had not of necessity the remotest connection with the Department. Upon the district inspectors' shoulders there rested the special responsibility of establishing, maintaining and terminating quarantine in every case of infectious disease regardless of its importance. To let memory dwell on the weary daily grind produces even now a most unpleasant taste in one's mouth, for the carrying out of the countless details considered essential to the proper surveillance of infection at that time ne-

cessitated from six to fifty calls a day, depending upon the season, in a district of considerable size. In this connection, it should be remarked that there is a tradition firmly planted in the mind of the medical inspector that infectious diseases show a marked affinity for the child whose habitat is the top floor of a lofty tenement.

In addition to his more or less legitimate tasks, there were all kinds of odd jobs, outside his regular sphere, which the inspector was called upon to perform, and irritating to the last degree were the frequent and peremptory orders 'phoned him at any and all times, and for little reason, to report forthwith at Headquarters. There was in fact no noticeable disposition on the part of the powers regnant to realize that we could not live on our meager salary alone and that we must needs bolster up our income by further sweatings of the brow in other fields of medical endeavor. Truly the forty hour week with Saturdays, Sundays, and holidays free had not been thought of in that benighted age, but had any one proposed such a progressive measure, it seems certain that it would have carried unanimously!

### Diagnostician's Office Created

Less than a dozen years back, there appeared on the scene a new member of the medical inspector family, the district diagnostician attached to the Bureau of Preventable Diseases. He is a by-product of one of our periods of reorganization and includes in the scope of his operations a few of the functions of the former district medical inspector and most of those of the former diagnostician, both of whom he has superseded. At the time of his induction into office, the multiplicity of irritating jobs which had until now sorely vexed the soul of the district inspector, were passed along to that hard working, capable, and invaluable departmental ally, the field nurse. Now if the nurse feels badly about it, she has so far, with the patience characteristic of her kind and in decided contrast to that representative of the male persuasion from

whom she inherited her troubles, refrained from becoming vocal.

Relieved of so many hindrances to his peace of mind the diagnostician responds each day to numerous requests for diagnosis in puzzling cases of infectious disease and, when necessary or advisable he has the infected patient removed to one of our hospitals caring for such conditions: when asked, he immunizes against diphtheria, typhoid fever, and tetanus; he vaccinates contacts and near contacts to smallpox and keeps exposed individuals under observation during the incubation period of the disease; he looks up certain special complaints and likewise tries, as did his predecessor, to soothe the ruffled spirits of harried citizens. A busy official, certainly, but the present day authorities apparently allow for the fact that a man, even though a department employee, has a right to live. Consequently, if he performs his duties properly he gets no pre-emptory orders to report, nor does he, except in emergencies, have to anticipate calls on his time outside of his regular work. One may deduce, though, from the synopsis of official duties detailed in the preceding paragraphs that for the district diagnostician or his forerunners in office to do conscientious work for the city and, at the same time attend to the demands of private practice, requires a speed of foot, an agility in climbing stairs, and a degree of all round hustling which is entirely beyond the ken of the average man.

Let us delve again for a moment into the past and speak of a form of departmental activity without mention of which no account of the work twelve to fifteen and more years ago would be complete. I refer to a specially obnoxious form of nightmare known as the smallpox vaccination raid on lodging houses, a procedure now a little out of fashion, but with a threat of its revival in some form always with us. The method of conducting these raids was simple and to the point. The inspectorial body foregathered at headquarters about two a. m. There each individual inspector obtained his vaccination supplies, was assigned to a lodging house, and having been allotted a police officer, went to his appointed, place, usually on the Bowery.

To the policeman fell the honor of heralding our arrival which he always did in approved style by hammering violently with his night stick on the floor of the dormitory and yelling in stentorian tones "All up to be vaccinated." And they got up

too and were vaccinated one and all, without regard to race, color, creed or previous condition of servitude, and in spite of fervent pleas for exemption based on every imaginable ground. These outings, needless to say, were not popular with us, and certainly the *hoi polloi* as represented by the guests at these hostleries gave no marked evidence of joy over this practical application of preventive medicine to their persons. In truth, it is not too much to say that the looks with which they transfixed us, the muttered imprecations, nay, more, the loud voiced maledictions hurled forth by some of our victims, inspired us with one desire, to depart with all celerity. In seriousness, it should be added that in face of conditions existing at that time, these raids, if unusual, were necessary and effective measures in the campaign against smallpox.

#### Sees Wide Range of Diseases

It is to be doubted if the medical profession at large has any conception of how many cases of infectious disease pass in review before the eye of the diagnostician, nor of what a wide and striking range of eruptions he encounters in his day's work. Not long since, for example, one of our doctors saw in a single day a very severe case of varicella in an adult (reported by the way, as smallpox), a case of endemic typhus, one of anthrax, an atypical attack of scarlet fever, and a wonderful exhibit of that form of skin disease known as Herpes Iris. Such a variety of assignments is not at all exceptional. In a service of even moderate length the diagnostician will see scarlet fever, measles, rubella, diphtheria, and varicella in immense numbers, and will become familiar with the characteristic features of variola, acute anterior poliomyelitis, meningitis (both the epidemic and tuberculous forms), and to a less extent of anthrax, endemic typhus fever, tetanus, and leprosy. The rarer types of infection cross our paths at intervals, among them that terrible disease, hydrophobia, which he it said in spite of many a doubting Thomas within and without the profession, is a distinct clinical entity, and once seen, is apt to be ever afterward recalled with a shudder.

In addition to this impressive array of infectious diseases, we meet innumerable cases of the non infectious dermatological conditions, and especially common are the eruptions due to intestinal toxemias or to drugs which can be conveniently classed under

those terms which are very dear to the heart of the diagnostician and which likewise may cover a multitude of sins, erythema multiforme and toxic dermatitis. As for the rashes which show a deviation from the accepted or text book type, their name is legion, and no sooner does one arrive at that contented state of mind wherein he feels that there is nothing more to learn about eruptions than a mysterious stranger appears to plague and puzzle him for a while, perhaps forever. The shelves of memory are well stocked with such instances and we really come to feel at times that so far as the exanthemata are concerned, there is no such thing as a consistent, dependable clinical picture. Surely, the zest and spice which variety adds to everything is found here in superabundance and most of us, even after years of this sort of toil, own up to a pleasant sense of anticipation as we approach a new case for diagnosis.

Do we make mistakes, does someone ask? We do. We admit it unblushingly, but while thus admitting it, we hear with amazement, and with amusement too, of that medical phenomenon who never makes an error in his diagnosis of eruptive diseases. The infallible diagnostician in this line of work exists only in fevered imaginations.

A glance backward through the years of the twentieth century already gone brings to mind some events which are of special interest to the epidemiologist. There was the smallpox epidemic of 1900-1902, a stubborn hard-fought affair which was finally controlled by a far reaching vaccination campaign carefully planned by our health authorities and systematically carried out by the inspectors. The infantile paralysis epidemic of 1916 was not impressive from the standpoint of numbers attacked, but the unprecedented mortality, the large proportion of permanent deformities which persisted in those who survived, and the atmosphere surcharged with terror which surrounded the houses in which there were children made it a memorable time for all who participated in that long summer's fight. The influenza epidemic of 1918-19, the greatest of all our scourges, with the recurrence of the disease in modified form the following winter is too recent a happening to call for special comment. In addition to these formidable outbreaks, there was an alarming flare-up of epidemic cerebrospinal meningitis in 1903-04, another of acute anterior poliomyelitis in 1909, not so severe

nor so well remembered as its more famous successor, and in other years we have experienced serious increases in the incidence of scarlet fever, diphtheria, and measles. It has of course been principally on the practical workers in the field, both male and female, that the heaviest task of handling these much dreaded visitations has fallen, and it is only just to say that with rare exceptions they always respond to the call of the emergency with fine spirit and with a most commendable intentness of purpose.

### Medical Discoveries

In this period, too, we have seen diphtheria antitoxin which, strange to say, was regarded twenty years ago still with considerable misgivings, achieve its deserved place in lay as well as medical opinion as one of our most valuable curative and preventive agents. And we have seen brought forward two epoch making discoveries in the field of preventive medicine. The anti-typhoid vaccine we have helped to popularize in this community, and so commonly is it used nowadays that it is hard to realize that it came to our knowledge but a few short years ago. A still more recent addition to our armamentarium is the so called Schick test for determining the presence or absence in the individual of immunity against diphtheria. This procedure is now just at the threshold of its usefulness, but it is not difficult to foresee that in conjunction with the toxin-antitoxin mixture, it may very well in future years put a new aspect upon the diphtheria problem.

On the other hand, we have witnessed within the last decade the passing together with the bag of asafetida carried around the school child's neck, of another relic of a superstitious age, namely, routine fumigation as a terminal procedure in the handling of a case of infectious disease. No one will deny, of course, that fumigation has its important place in preventive medicine, but in this particular phase of the subject, for a most unpleasant smell at the conclusion of the attack we have substituted firm insistence on fresh air and cleanliness throughout the duration of the disease, with a thorough cleaning of the sickroom upon the recovery of the patient. The wisdom of this move is clearly reflected in the improved statistics bearing on secondary cases.

It seems unfortunate that the many new discoveries in medicine of late years have not been of a kind to make the work of diagnosing eruptive dis-

eases any easier. It is a fact that the diagnostician has to depend now as in the past on a good pair of eyes, a well balanced judgment, and particularly on common sense as the most important aids to the proper performance of his duties.

### Comedy Element Present

It has been aptly said that for a medical inspector of this Health Department to do his work efficiently, he should be able to talk and also to gesture in about thirty different languages. It is often most exasperating to try to obtain needed information from our foreign born population, but still more often it is highly amusing. It has many times occurred to the writer that could a comedian, say of Weber-Fieldian type, accompany him on his daily rounds, the said comedian would obtain fine material from which to furnish side splitting entertainment. An incident occurred about ten years ago, which was excruciatingly funny in its original setting. The story loses much in the telling, and it is related here more to give an idea of the hopelessly blank wall we often strike when looking for light than as an example of the humorous. A public spirited denizen of the East Side sent a communication to the Department, neglecting of course the little formality of signing his name, in which he expressed the opinion that it was an outrage that a leper was allowed to remain in a Chinese laundry on Rivington Street. Although there was probably no one in the city at the time who knew any less about leprosy than did the diagnostician to whom the complaint was assigned, there was no avoiding the responsibility for investigating the case. On reaching the laundry complained of, he observed two Chinamen working at ironing boards in a front room and on a box placed in a doorway leading into a back room sat a third Chinaman, dreamily smoking a pipe. To the query "where is the sick man?" the reply came from a nearby laundry man "nobody sick, no understand English," the character of which reply as a whole being such as to make the verity of any portion of it at least subject to scrutiny. Having thus replied, however, no one paid any further attention to the person or questions of the visitor. After wasting much time and more language in a vain attempt to establish an *entente cordiale* the diagnostician changed his strategy and adopted a new method of approach. Pinning his badge on the lapel of his coat, he sternly demanded

of the Celestial nearest him. "What is your name?" Evidently impressed at last by the glint of the badge, he promptly replied "Me? Me Hop Lee." Somewhat encouraged, our friend again asked, "Well, who is the fellow over at that other board?" "Him?" replied the Chinaman, "he Hop Lee." Satisfied now that his questions were really getting him somewhere the Health Officer finally inquired, "And who is that smoking the pipe?" "Him?" came the answer, "he Hop Lee too, allee samee Hop Lee." Having so freely tapped this clear spring of information, the diagnostician withdrew from the laundry for the purpose of searching for a policeman who in addition to his other accomplishments, might talk Chinese. In this quest he was not altogether successful, but he did find a husky gentleman of Hibernian descent who knew how to make these Chinamen display a perfect working knowledge of the intricacies of our Mother tongue, and after the whole company had communed together most affably for an hour or more, it was unanimously agreed that nobody had leprosy!

### Punitive Measures Necessary

That our quarantine regulations may not be made sport of, the Department finds it necessary from time to time to resort to disciplinary moves. One of our repressive measures which is always regarded by the citizen as a very potent *casus belli* is the forcible removal to the hospital of a patient suffering from an infectious disease because of inability to isolate properly or wilful indisposition to do so. The carrying out of this punitive act may on occasion result in a serious threat against the integrity of the limb and sometimes even the life of the medical inspector. To cite a case in point.

Sometime ago a child ill with scarlet fever was domiciled on the sixth and top floor of a Clinton Street tenement. The inspector in whose bailiwick stood this building was much peeved in spirit by the persistence and reckless abandon with which the mother of the child in question broke each and every rule of quarantine and gloried in the pastime. An early visit found the boy playing in the hallway, and the mother was warned of judgment to come. Another visit located the patient in an adjoining flat, mingling with some perfectly sound children. This violation of Department rules necessitated a call from the Health Squad policeman who advised the family,

with emphasis, to walk the straight and narrow road. A third visit disclosed the fact that the ubiquitous youngster was taking the air on Delancy Street. This was too much and there promptly ensued a forcible and likewise, according to reliable eye witnesses, a very tumultuous removal to the hospital.

The following day, as per custom, the medical inspector hied him to the premises for the purpose of looking over the disinfection. As he tells it, he magnanimously agreed with himself that he would not rub it in on these unfortunate people, but would be content with scattering around a few burning thoughts touching on the value of living up to the rules. So carefree and light of heart, he blithely began to ascend the stairs. At about the first landing, he noted the hum of distant conversation wafted down from above, but such hums being the rule in those parts, this particular hum attracted no special attention. As he mounted higher, however, the increase in volume of the conversational murmur carried with it the assurance that a matter of no mere passing importance was the subject of discussion further up. Entirely unconscious that he was in anyway connected with what was going forward, he attempted to negotiate the final flight of stairs. As he hove into the field of vision of the moderator of the town meeting which was being held on the top landing, a fearsome shriek greeted his ears,—a shriek in which the elements of ordinary rage, righteous indignation, and vengeance were clearly distinguishable. Immediately and with whirlwind velocity there descended upon him a feminine avalanche composed of the mother, relatives, and friends of the incarcerated boy, gathered from near and far against the hoped for coming of the "Board of Health." The startled inspector took one quick glance at the approaching menace, and rapidly overhauling the old adage that "discretion is the better part of valor," abruptly reversed his line of march and went away. To say simply that he *went* away, exhibits an extraordinary moderation in the use of the words to picture the manner of this ignominious debacle. The doctor avers with much feeling that he still is and ever expects to be most grateful that his long practice in the gentle art of going down dark, precipitous, and winding staircases at full speed without breaking his neck enabled him in this crisis to emerge from the stoop door triumphant and unscathed as to person, though much damaged as to

pride, a full length ahead of the maddening crowd. Need it be added that the environs of Clinton Street knew him no more until these storm clouds had blown away?

#### Even Strikebreakers Once

There have been times, too, of a sort to try men's souls, many of them, and chiefest among them all I would place a long summer evening in the distant past. Late in the afternoon we had received that order, the *bête noir* of the medical inspector, to hurry to headquarters, and having hurried we were sent *en masse* to Willard Park Hospital at 16th Street and East River. No explanations were forthcoming, but inasmuch as there was a street cleaners strike on at the time and as the stables of the street cleaning department were next door to the hospital, I believe that each of us had a premonition that all was not well. When, however, we finally learned what was planned for us, the most hardened veteran with a nervous system inured through many weird experiences to every form of shock known to science owned up to a feeling of unrest in the gastric region, while those of us who were not veterans were just plain scared to death. It appeared that it had been decreed that we should finish our several careers in the performance of the all-glorious and inspiring task of helping to break the street cleaners strike! We were not to drive a cart, nor indeed were we to hoist the contents of garbage cans aboard; all we had to do was to saunter along behind the cart from the source of supply to its destination, the dump, and this if you please between twelve midnight and daybreak. Had it not been for that pride of race indigenous to most humans, and the dislike one feels to listening to opprobrious remarks from fellow man in which the word yellow predominates, every one of us would have quit right there, without standing upon the order of our going. If any reader is unfamiliar with nocturnal conditions in that section of our city colloquially known as the Gas house district, let him take the word of one who knows that the atmosphere there at best is not salubrious. On the night in question, it was actively contaminated. The gentle hints dropped in our ears by the pickets infesting the neighborhood regarding certain replacements which were due the following morning in the personnel of the Department were not cheering; and the well founded rumor that the tenements and house-tops along Avenue C were stocked

with cobble stones, brick bats, clubs, and other missiles and implements of assault hard and rough, lent a sinister tinge to the heads which appeared at the windows and the faces which now and then peered over the coping of the roofs.

Experience that night, together with much more picked up in years of this service, demonstrated very satisfactorily that things in reality are never as bad as they are in anticipation. The *dénouement* in this case was as sudden as it was unexpected. Just before midnight when things around us were becoming unpleasantly active, the absolute silence which had until now pervaded the interior of the stables where the strike breaking drivers were assembled for safekeeping was suddenly replaced by a violent and noisy outbreak; the doors of the stable burst open and there erupted with a wild yell a compact mass of about a half hundred of our prospective associates. Enveloped in dust and darkness they quickly vanished in the general direction of 23rd Street and Avenue A followed by a shower of heartfelt benedictions from a most relieved body of medical inspectors. So happily ended our first and, so far, our last assignment to strike breaking duty. And so it goes from day to day.

It has been possible in the limits of this paper to give little more than a snapshot at a very big subject. The writer has, however, endeavored to demonstrate that the life of the Department of Health physician, so employed, is not a humdrum affair, but is on the contrary full of variety and action; that he frequently encounters those rare conditions in the field of infectious diseases which may easily escape the notice of his professional brother outside in long years of practice; and, finally, that if he has his heart in his work and is possessed of even a moderate sense of humor he is well repaid for his arduous labor, by the interesting, valuable and oft-times amusing experience acquired as he goes about his work.

#### Speech Training for Soldiers

Under the reorganization of the Rehabilitation Division, U. S. Veterans' Bureau, Washington, D. C., the training of ex-service men with defects of speech and hearing has been placed under the direction of Mr. Arthur Holmes, supervisor for the blind. The central office regional representatives for the blind will supervise the training of the deaf and those having speech defects as well.

# Dyestuffs and Disease

BY OUR LONDON CORRESPONDENT

WHAT intoxications resulting from infective processes are probably responsible, directly or indirectly, for nine-tenths of the suffering and misery consequent upon the ravages of disease was the thesis of a paper jointly presented by Dr. Arnold Renshaw and Thomas H. Fairbrother, M.Sc., before the recent meeting of the Society of Chemical Industry held in Manchester. Thus, the greater proportion of heart and lung diseases are bacterial in origin. Rheumatism is due to a toxin derived from organisms growing, it may be, in remote organs; peritonitis, pleurisy, meningitis, present a definite bacteriology. When, however, disease is recognized by its cause rather than by the organs affected, then the truth of the statement becomes clearer. Thus streptococci for instance, can produce inflammations of many organs. The infective diseases could be classified roughly into:

(1) Those with unknown infective origin, such as chickenpox, measles and scarlet fever.

(2) Parasitic infections, by the Protozoa, causing such diseases as malaria, sleeping sickness, or dysentery, and the Metazoa, such as flukes, filaria, and worms.

(3) Bacterial and fungal diseases, such as actinomycosis, anthrax, diphtheria, tuberculosis, "septic infections," typhoid, and many others. In all, some fifty specific diseases were mentioned, of these the causative agents were not yet discovered, in twelve of the remaining thirty-eight a partial successful curative agent was available, in ten. There are thus twenty-eight diseases in which the causative agent was known in which there was as yet no "direct attack" method of treatment. To these must be added the twelve diseases of unknown causation, since they are known to be infective.

There were, therefore, forty important diseases for which it could be truthfully said that no real curative agent exists apart from the body resistances. When a person became ill it was by the toxins resulting from the rapid proliferation in the blood or tissues of the bacteria or parasites responsible for the attack. In the case of a bacterium each microbe could be potentially divided under favorable conditions every twenty minutes, so that from a single bacillus within twenty-four hours many millions could be obtained. At the same time the body tissues were producing specific antibodies which tended to kill off that one type of organism and that

one type only. After an attack, the blood was richer in these antibody substances, hence the immunity for a time from further infection. It was hoped to prepare in the laboratory, possibly on a much coarser scale, chemical substances which should have a similar direct action on infecting agents. These substances must not be harmful to the patient, although highly lethal to the infective agent. Ehrlich has expressed this in a flash of genius in the words "parasitotropic but not organotropic." When an infection occurred these possibilities arose: (1) The organism was rapidly killed off by the chemical antibodies and cells in the blood; (2) the organism killed the patient; or (3) a gradual balance was established in which the infection became localized, but from time to time the body became flooded with the toxins, causing chronic ill-health. There were two methods of fighting such an infection: (1) by coaxing the body itself to fight the infection by means of rest, with warmth, etc.; (2) by injecting into the blood chemical substances having a chemical affinity for the infecting agent, which could kill that agent quickly and cleanly without harming the tissues and organs of the body.

The present work, the authors explained, had been a study of these chemical affinities—fourteen of the commoner organisms had been employed in work and certain Protozoa. These were: *B. phloei*, *B. subtilis*, *B. anthracis*, *B. diphtheriae*, *Streptococcus*, *Staphylococcus*, *B. coli*, *B. dysenteriae* (Shiga, Flexner and Gaertner), *B. typhosus*, *B. paratyphosis*, *A. B. paratyphosus*, *BB. Lactic* of the Protozoa. An actively mobile paramoecium was used and occasionally certain flagellates. These organisms had been tested with different dilutions of the various dyes used. As a result a mass of useful information had accumulated, some of which would probably be of immediate application, some of which would require further development before final application could be made. Certain dyes showed a selective action which would be useful.

Thus, one of the difficulties associated with the activated sludge process of sewage purification lay in the fact that the Protozoa after a time increase too rapidly in numbers and, presumably, eat up the bacteria responsible for the purification process.

Several dyes had been discovered which would kill the Protozoa in high dilution, without harming the bacteria. As an example of the way in which the knowledge now gained can be utilized, an interesting experiment was quoted. The authors wished to test certain dyes on the worms present in the blood of a patient suffering from bilharziasis, a tropical disease of West Africa for which no cure exists. They were put in touch with two cases who presented themselves for examination. The first patient was examined and his blood was found to contain the tiny moving worms present in the blood in this condition. A solution of a dye was made and mixed with the patient's blood until a dilution of one in four thousand resulted. The blood was again examined and the *Filaria* were seen to be still moving, but within five minutes of mixing the dye with the blood they became dead. The whole experiment had taken up but fifteen minutes to complete and within this time the patient had the satisfaction of knowing that at least one substance existed which had a lethal action on his parasites. It is believed that this drug may possibly be administered intravenously. Similarly, some of the more powerful dyes are being tested out as antiseptics now on the human being in regard to suppuration in the nose and in the eye, and arrangements are being made for their action in cases of gonorrhoea. In this work eminent surgeons are collaborating—animal experiments are also being conducted to ascertain which of these dyes may be given intravenously. In regard to syphilis, Ehrlich had produced a substance, salvarsan and neosalvarsan, for the treatment of this disease. The authors had tested neo-salvarsan in a dilution of one in two hundred against one of their test Protozoa and found them to be alive even after two hours immersion in this solution. They have obtained dyes which killed this same test agent in a dilution of one in two thousand instantly and one in twenty-thousand within fifteen minutes. Mixtures of dyes had been tested and even the range had been increased, action being observed up to a dilution of one in eighty thousand instantly and up to one in a hundred and sixty thousand within fifteen minutes.

In addition to these chemical applications and to the sewage application there are possibilities of antiseptic action, these substances being employed in connection with certain foods and beverages such as milk. With respect to the purely chemical

side of the subject, the central idea which the authors had kept in mind had been the actual part played by different chemical groups in antiseptic action among the various classes of coal-tar dyes. The work done has covered broadly the whole range of coal-tar colors and antiseptic action has been studied in the following classes of dyes:—Azo class, triphenyl methane class, phthaleins or pyronins, azarins, including oxazine, safranines, thiazines, eurhodines, acridine, in short all the dye classes whose members are water-soluble. Representative members of each class have been studied in their action on fourteen common organisms and also in their action on living Protozoa.

The results show that there are certain classes which have a greater or less tendency to antiseptic action, such as the triphenylmethane class, the safranin class, and acridin class. The azo class as a whole showed very little antiseptic action. In each group there is an internal variation of antiseptic action, which action can be controlled by varying substituent groups in the type molecule. Then in the triphenylmethane class certain strongly basic dyes, such as crystal violet and cyramine, etc., showed very strong antiseptic action, whereas others, such as the patent blues, acid greens, turquoise blue and Victoria blues showed very little action. This is due to the fact that in the latter type different groups are on the nucleus, which removes the antiseptic properties manifested by crystal violet itself. The experimental work has revealed the fact that certain dyes have a definite selective action and attack some organisms and leave others alone.

This is extremely important as it opens up a field of work which should result in the fixing of certain dyes for certain organisms, and one can find which substance may be most suitable for a disease brought about by definite organisms. Certain other dyes exhibited a selective action between Protozoa and bacteria, and kill the former, but do not injure the latter. This also is important for such operations as require the partial sterilization of a mixture of bacteria and Protozoa, as in sewage treatment. The authors point out that while chemical constitution undoubtedly plays a big part in antiseptic action, and while the presence of certain groups in the molecule can prevent antiseptic action being shown, there are probably other factors to be considered as well. Most of the dyes showing antiseptic action diffuse rapidly through parchment and belong to

the class of substance known as molecular dispersoids, whereas, those which do not, show much antiseptic action form jellies or colloidal solutions. It is possible that the rate of diffusion of the dyestuff into the cell membranes has much to do with the problem and the choice of antiseptics must be governed by these considerations. Another point of considerable moment established by the authors is that where a dyestuff exhibits antiseptic properties, these properties can be augmented by the introduction of a metallic salt of the same acid as the dyestuff into the molecule of the dyestuff as a double salt. Thus the double salt of zinc chlorid and crystal violet chlorid is a more powerful antiseptic than either crystal violet chlorid itself or zinc chlorid itself.

In commenting on the original piece of research work it may be said that it has been predicted more than once within recent years, that most diseases have a chemical origin and that therefore their rational treatment is by chemicals. Treatment by colloidal therapy, which has met with a good deal of success, is a step in this direction. The coal-tar dyes have long been known to possess certain therapeutic virtues, and it has been held, or rather

suggested, by some that some dyestuffs in dilution have strong antiseptic properties and are able to destroy bacteria, Protozoa, parasitic, and fungal diseases, indeed the causative agents of any of the infective maladies. Dr. Renshaw and Mr. Fairbrother have been investigating along these lines for some time and many speculations, too optimistic for the most part, have been advanced as to the results of these investigations.

Although the speculations of their friends were too rosy, it will be gathered from their paper that they have discovered that it is the property of certain dyestuffs, when in high dilution, to kill speedily the Protozoa or parasites in syphilis, filariasis, and diseases of a like nature. At any rate, this is a progressive movement and augurs well for the future of the dyestuffs as a means both of preventing and treating diseases of an infective character. Of course, all the work done up to the present time has been experimental, and much further work will be necessary before dyestuffs can be confidently used as a preventive or curative agent. However, as said before, sufficient has been done already to encourage high hopes in dyestuff therapy.

## City and World Health

A CANVASS recently made of the doctors in the city of New York in an effort to further the movement to coordinate existing medical institutions and organizations and to enlarge their clinical facilities was the subject of recent editorial comment in the *New York Times*. The object of the survey is not only to get rid of duplication and to make more effective the work of the hospitals, but also to attract graduates of medical colleges throughout this country and even physicians from other parts of the world. The great medical colleges of Columbia, Cornell, and New York University, the Long Island College Hospital, and the New York Post-Graduate Medical School are all represented in the Board of Directors of the Association for Medical Education.

The *Times* comments thus on the situation:

"When we were asked by the League of Nations to participate in a conference of its International Health Section called especially to standardize antitoxic serums for fighting certain diseases the earth around, it was understood that the invi-

tation to our Government suffered the fate of the earlier communications from the League of Nations. But this invitation finally reached a Federal health official, who caused a delegate to be sent to this conference. This representative had to be careful, however, to make clear and emphatic that his presence in no way associated our Government with the League of Nations. He participated, nevertheless, in the deliberations, with the result that in the allocation of serums to the laboratories of the several participating countries for special study and standardization two (those of tetanus and diphtheria) were assigned to the United States."

Now, is there any good reason, asks the *Times*, why we should not send official representatives instead of "unofficial" delegates or "observers" or circumlocutory spokesmen to this and other like humanitarian conferences, even though they were created or adopted by the League of Nations? Should not Congress be asked to make it possible for the United States to join in these humanitarian efforts directed against the menaces of disease and other enemies of mankind that

## Ontario Health Resorts

By JOHN W. S. McCULLOUGH, M.D., D.P.H., CHIEF OFFICER OF HEALTH, PROVINCIAL BOARD OF HEALTH, TORONTO, ONT., CANADA.

THE chief Summer resorts of Ontario are found in five regions, (1) the Rideau Lakes, extending from the neighborhood of Kingston to near Ottawa; (2) the Thousand Islands at the head of the St. Lawrence; (3) the Kawartha Lakes in the central portion of Ontario; (4) Algonquin Park, a great natural preserve in the central northern portion of the Province; and (5) the

treatment by live steam for one hour. The contents so sterilized are then dumped at a safe distance from any wharf or place of residence. In addition to the regular inspection the District Officer makes frequent return visits during the season to check up any improvements ordered by him.

As a result of these careful and systematic inspections which have been carried on during the last twelve

few mosquitoes during the Summer resort season and where any at all are found they are considered innocuous so far as disease is concerned. In some places there are too many flies, but proprietors of hotels are learning that it pays them to take measures of protection against the fly nuisance and the result has been to a great extent the absence of the manure pile.

The weakest point about these resorts is the milk supply which, in some quarters, is not pasteurized. We hope soon to educate all the keepers of health resorts in the value of this measure.

The Board does not know of a single case of typhoid developed in an Ontario health resort last season.

### Organize Illness Prevention Service

A community experiment started with an anonymous gift of ten thousand dollars, which fund is to be augmented by membership fees of six dollars per person per year, is being conducted through the organization of the Manhattanville Health Society. Residents to the number of about 73,000 have organized to purchase an illness prevention service and the services of visiting nurses should illness come. The service includes a clinic, or center from which is procurable advice on all matters pertaining to health.

Boats plying upon the waters adjacent to summer resorts are required to provide tankage for their sewage, in which the contents are subjected to sterilizing treatment by live steam for one hour and then dumped at a safe distance from any wharf or place of residence.

Muskoka Lakes and Georgian Bay regions.

All of these resorts are very attractive and efforts are made by the Provincial Board of Health to improve and maintain the local sanitary conditions, particularly in respect to water supplies and the disposal of sewage.

It is an offense under the laws of Ontario to discharge garbage, excreta, manure, vegetable or animal matter into any of the lakes, streams, rivers or other waters, or to deposit any of these materials on the shores or banks of these waters. Owners or officers of all boats plying upon these waters are forbidden to discharge any of these materials into the waters.

All Summer resorts are inspected by the officers of the Board early each season, and under the law the Board has extensive powers whereby purification of public water supplies and treatment of sewage may be enforced. The boats plying upon the waters adjacent to Summer resorts are required to provide tankage for their sewage in which the contents are subjected to

years, substantial improvements in sanitation have been secured. In general, the water supplies may be considered safe, the disposal of sewage is in the very great majority of cases adequate and satisfactory; there are

All summer resorts are inspected by the officers of the Board early each season and efforts are made to improve and maintain local sanitary conditions, particularly in respect to water supplies and the disposal of sewage.

## Digest of Sanitary and Hygienic Advance

**P**UBLIC health activities are so largely concerned with mass observation and statistical method that oftentimes disease control seems to resolve itself into problems of administration. The silent, patient inquiry of the laboratory, however, must ultimately point the direction of preventive effort and the far sighted health worker will avail himself of every opportunity to keep in touch with the vanguard of laboratory research workers.

**The Transmission of Herpes.**—The work which is being done in the endeavor to prove or disprove the etiological identity of chickenpox and herpes zoster has opened up a new vista of epidemiological thought, bearing as it does on the larger question, the virus diseases in general. During the last three years, a number of investigators have made research into the subject of the other varieties of herpes, and while it is too early to accept or reject their various findings, those who desire to maintain an unbroken continuity of contact with the development of the science of sanitary medicine from a bacterial age into a virus era will find peculiar interest in the report of Milian and Brodier in their annual (1922) review of dermatology (*Par. Med.* xii, No. 8, Mar. 8-22, p. 221 et seq.) in which they discuss the etiology of febrile herpes from the viewpoint of its infectious nature. The portion of their article which refers to herpes is of such interest to health workers that a considerable portion is here translated:

Gruter in 1913 inoculated the cornea of the rabbit with material from a human case of herpes: Loewenstein in 1919 inoculated the serous fluid of various herpes: these results were confirmed by the work of Dörr and Vöchting, Dörr and Schnabel, and Luger and Lauda. The infectious nature of herpes has been demonstrated by the experimental researches of Blanc and Caminopteros and by those of Levaditi, Harvier, and Nicolau.

The contents of a vesicle of labial herpes produces upon the rabbit's eye, either before or after filtration through a bougie, an intense keratoconjunctivitis which may be followed by a fatal encephalitis. This keratoconjunctivitis is transmissible in series and confers a certain local immunity although the other eye is not immune. Genital herpes is equally infectious: its virus produces upon the eye of the rabbit the same effects as those of buccal herpes but the contents of the vesicles of herpes zoster similarly inoculated produce no effect. The virus of herpes inoculated into the dura mater of the rabbit produces a

fatal encephalitis comparable to that which follows the sub-dural inoculation of epidemic encephalitis. A pronounced local reaction of the inoculated eye may immunize the animal against a subsequent sub-dural inoculation. The inoculation of the rabbit's cornea with the cerebral material of rabbits dead of herpetic encephalitis reproduces a typical keratitis. The herpetic virus is rapidly destroyed by bile, as is also that of epidemic encephalitis. The skin inoculation of the virus of epidemic encephalitis provokes in rabbits a papulo-squamous dermatitis containing the virus of the disease, and which is followed, probably by the invasion of the terminal filaments of the cutaneous nerves, by the death of the animal from encephalitis. The serum of rabbits immunized against the herpetic virus and of patients attacked or cured of epidemic encephalitis had no reaction from the virus of herpes. Dörr and Schnabel found the latter in attenuated virulence in the saliva of subjects having had herpes. Levaditi and his collaborators also found it constantly present in the saliva of a healthy subject.

The virus of herpes is identical with that of epidemic encephalitis but it is more dermatotropic than it. According to Levaditi, Harvier and Nicolau, the virus of herpes, the salivary virus, and the virus of encephalitis are nothing more than variants of unequal pathogenic powers of the same germ, the encephalitis ultra-virus. This ultra-virus has, as do those of vaccinia, rabies and poliomyelitis, an elective affinity for the tissues derived from the ectoderm (cornea, skin, and nervous system) and for the superior segments of the ectoderm (buccal and naso-pharyngeal mucosa). Levaditi proposes to call the disease-group produced by these ultra-viruses "neurotropic ectodermoses."

**Cats as Disseminators of Itch.**—Sanitarians generally, and the public in part, are beginning to realize that the exclusion of other living species from the immediate environment of man is an essential to health. It has been recognized for a considerable time that domestic animals play a not inconsiderable rôle in the transmission of itch, although, singularly enough very few of the classical treatises on human dermatology devote very much space to the subject. Thibierge, (*Par Med.*, xii, No. 11, Mar. 8-22, p. 229 et seq.) who has studied the transmission of feline sarcoptic itch to man for the past twelve years believes that it is of far more common occurrence than has been hitherto recognized. Two species the *Sarcoptes notoedres Alepis*, which has also been in rats and mice, and the *Sarcoptes notoedres* Med., xii, No. 11, Mar. 8-22, p. 229 et

latter species occurs in the varieties *cati* and *cunicula*. The author gives a complete description of them. They are transmitted to man by direct contact with cats, or indirectly from articles on which the infected animal has rested. Direct transmission is facilitated by the fact that in the cat the lesions are most frequent on the head and ears. While the cure of the disease is not difficult in the hands of a skilled dermatologist, its presence is an economic and aesthetic handicap. From a public health viewpoint, cats are better kept outside the human habitation. At any rate, they should be admitted only if they are clean and in good health and then they should not be fondled or permitted to occupy beds in which people will subsequently sleep.

**Rodent Destruction.**—Before using the bacterial viruses for rodent destruction, it should be recalled that plague is the most fatal bacterial disease to which the rat is subject, yet despite the widespread geographic distribution of that disease, the rodent specie still flourishes.

**Epidemic Encephalitis.**—Slight ptosis followed by drowsiness and diminished sensitiveness of the cornea are very early symptoms of epidemic encephalitis.

**Maternities as Anti-Syphilitic Centers.**—A considerable number of expectant mothers suffering from venereal disease do not seek dispensaries for the treatment of their infection. It has been found in France that the careful examination and treatment of all such persons admitted to maternities has yielded excellent results. The opportunity to give prompt treatment to the newborn child is especially valuable.

**Birds as Indices of HCN.**—Birds are sixty times more susceptible to the poisonous effects of hydrocyanic acid gas than is man. When using that agent as a fumigant, a bird in a cage should be introduced into the compartment before human beings are permitted to enter.

**Per Orum Vaccination Against Malta Fever and Shiga's Bacillus.**—Nicolle and Conseil stated before the French Academy at its session of March 13, 1922 (*Par. Med.* XII, No. 12, Mar. 25, 1922), that they have experimented with the digestive tract as a portal of entry for vaccinating against several human diseases. An experiment was made with Malta

fever and the results obtained seemed to be as good as those following subcutaneous injections. Attempts at vaccination against Shiga's bacillus in the same manner seem to have given identical results. Rabid anti-vaccinationists of the future will probably complain that some evil-minded doctor has been slipping some vaccine into their tea.

**Improved Method of Staining Tubercle Bacilli in Thick Smears.**—Stain the specimen with hot carbol-fuchsin and discolor with

Absolute alcohol .....	80
Nitric acid .....	20
Formol .....	100

This solution should be freshly prepared and applied until complete decoloration of the specimen occurs, then wash in water, dry and examine. Bacilli are stained violet on a pink field and it is claimed by C. Picado T., who has evolved and used this method in the Laboratorio de San José, Costa Rico, for several years, that by this procedure the exploration of deep fields is much facilitated.

**New Diphtheria Immunity Test.**—The *Weekly Bulletin* of the California State Board of Health (Vol. 1, No. 9, Apr. 15-22), Dr. W. H. Kellogg, Director of the Hygiene Laboratory of the California State Board of Health, has devised a new diphtheria test which possesses many distinct advantages over the Schick test, especially for individuals or small groups. The technic of the test will shortly appear in another publication, but it is stated that physicians who desire the test made have simply to send to the laboratory a few drops of blood folded in a sheet of tinfoil as are specimens for the Widal test.

**"Visiting the Sins of the Fathers."**—Health officers who are actively carrying forward anti-syphilitic measures will find interest in the following disgenic chart which tells its own story:

A couple now aged 58 and 56 years respectively were married 38 years ago; the first four pregnancies resulted in the birth of four normal children, three boys and one girl, all of whom are now living at the ages of 37, 34, 31, and 29. Soon after the birth of the last child in this first group, the father contracted syphilis in extra-marital congress. Out of the

six succeeding pregnancies, there are three living children, of whom one is healthy, one is badly deformed, and one is a chronic bleeder.

**Put the Birth Certificates to Work.**—How many health officers pay any attention to the character of the obstetrical work which is being done in their community except perhaps to hector some ignorant mid-wife who should not be attending confinements anyway? According to the *Health Nuggets-Fillers* of the U. S. Public Health Service, "more than 100,000 of the 250,000 children less than one year old who die every year in the United States, die from causes connected with their birth. The need for further study and investigation of these causes is urgent." This is true as "God's in Gloucester" but in the meantime the babies are dying and the health officer has the weapon in his own hands. There should be a follow-up visit on every birth certificate by the health nurse, thus making it possible to check up accurately on the kind of obstetrical work which the public is getting and to take steps to eliminate those who are doing careless and therefore dangerous obstetrical work.

**Test for Cure in Leprosy.**—Before paroling lepers whose lesions have cleared up after treatment, it is wise to administer potassium iodid and observe carefully the resulting reaction. Many apparently cured cases will show a return of skin and nerve lesions following this test.

**Freedom(?)**—The results of the persistent, organized anti-vaccination propaganda should be a source of great satisfaction to all who have had a part in freeing our country from the awful scourge (?) of vaccination which a selfish and misguided medical profession thrust upon it. It is true that in several states, the number of cases of smallpox in 1921 was more than double the number in 1919, that the case-fatality rate has increased 50 per cent, that while most of the cases occurring at present are relatively mild, the disease is increasing in virulence and may assume the malignant type at any time, and that all of this is costing the United States much money, not to say making many aching hearts and pock-marked faces. But what does this matter to the anti-vaccinationist? What does he care how many foolish persons run the risk of having their children killed, or disfigured for life? What he wants is FREEDOM! and the freer it is the better he likes it! He wants a country where anybody shall exer-

cise his God-given right to spread disease, where any mad-dog may roam at will, where anybody who kills an anopheles mosquito shall be guilty of a misdemeanor, where the tuberculous may expectorate where and when they will, where any person with a venereal infection may marry, a country where no one may say to another person, "You shall not endanger the health of the community. If you haven't sense enough to protect yourself against disease, the community will do it for you, for its own self-protection." The voters who supported the anti-vaccination amendment proposed at the 1920 elections should feel much satisfaction at the fact that in 1919 there were 940 cases of smallpox in Alabama as against 2,712 in 1921, while in California the annual number rose from 2,053 to 5,580, in Iowa from 1,794 to 5,774, and in Minnesota from 2,449 to 9,375. This is a wonderful record!

Native Stock Dying Out

Sanitarians of the Michigan State Department of Health who are making studies of births among persons of native and foreign parentage find that during 1921 the foreign groups in Michigan increased 5 per cent faster than did the native Americans. Of the 95,932 children born in the state in 1921 more than two-thirds, or 63,618, were born of native American parents. The remainder, or 32,314 children, had either a foreign father or mother, or foreign parentage on both sides.

Taking the number of native and foreign women in Michigan between the ages of fifteen and forty-four—the child-bearing age—it was possible to secure accurate comparisons showing the number of children born to every one thousand women in each of the two groups. This would illustrate the relative fecundity of native and foreign stocks.

On an intercensal estimate it was found that in 1921 there were 371,600 native born women between the ages of fifteen and forty-four, and 172,300 foreign born women of the same ages. To every group of 1,000 women of native American stock 178 children were born during 1921, while for every one thousand foreign born women there were 188 children born, giving the foreign born stock a birth rate 5 per cent higher than that of the native Americans. Detroit reported 27,613 births in 1921. Of this number 14,050 children were born of foreign parentage and 13,563 of native American parentage.

a live topic of discussion by the doctors in the convention.

The same thing held true also to a less degree of the narcotic prescriptions. Many doctors felt that some change should be made in narcotic regulations.

By far the greatest interest was shown in the implications of group medicine and state medicine in the Sheppard-Towner Act. It was evident that the physicians in attendance at the convention were heartily interested in it and that practically all of them had definite opinions in the matter.

To the observer it is quite evident that these three questions cannot be solved at one conference and that the next annual convention of the American Medical Association will witness a very hot discussion of these questions. As time goes on, doctors are awakening to the fact that the attitude of the public toward medical activities must be ascertained, at least on basic matters and that the doctor can no longer limit his interests to the particular group of patients he is treating.

Whether or not the newer tendencies in the line of social medicine will gain ground is hard to foretell. Certain it is that questions of public health are entering more and more into the realm of the American Medical Association.

## Hospital and Community Relationships

THE hospital whether public or private, may in quite an important sense be considered as a health plant. It is the one single institution from which radiates a complete service—surgical, medical, social, investigative, preventive—and is the logical unit of such extensions as modern methods and modern social consciousness seem to demand. The community phases of hospital service are well set out in the definition of a hospital given in the report of the Committee on the Training of Hospital Executives, just issued:

The hospital may then be defined as a community organization which provides facilities and personnel for rendering the highest possible grades of health service to patients, professional groups, and the community; for educating the community to demand and support adequate health services and sound health policies, for educating additional personnel and professional groups in technical fields, and in cooperative endeavor; and for advancing knowledge of disease and its prevention through technical research and appropriate organization.

The subject matter required for the basic training of a hospital administrator needs to be diversified and, according to the Committee, could well devote much more time than has been given heretofore to public health and the social sciences. Preliminary training could well devote fifty per cent of time now devoted to strictly hospital topics to questions relating to public health, the social sciences, and to organization.

## The American Medical Association Takes Its Bearings

THE convention of the American Medical Association held at St. Louis May 22-27 distinguished itself from many former conventions in that the voice of the masses was heard in many matters of legislation and general welfare of the medical profession. It used to be the custom of the men and women attending a medical convention to attend the session of some particular section, attend also the various functions staged by the committee on arrangements, and return home without a knowledge of what had been going on in the house of delegates.

This year matters changed considerably. No matter how scientifically inclined a person might be, he not only attended the meeting of a particular section but also lent his ear to what was going on in the House of Delegates. The reason for this is apparent. At no time, have so many questions concerning the doctors and the general public been brought up before the house of delegates. The question of prescribing alcoholic liquors which seemed entirely solved with the Volstead amendment to the constitution has been thought by many doctors to be inadequate. Some considered it too limited in its application as far as the medical practitioner is concerned, and others saw it in loop holes for abuse by a certain class of people. This question which was the subject of more than one resolution in the house of delegates was

## Coordination of Forces in Public Health Campaigns

**I**N a relatively new field like that of public health, the problems involved in the development of a constructive public health campaign extend far beyond the internal organization of the official health department. It is indeed essential to plan wisely for the apportionment and the expenditure of a health appropriation of the city and the state; such attempts at standardizing official procedure as are being made by the Committee on Municipal Health Department Practice of the American Public Health Association are of fundamental importance. It is almost equally important, however, to provide for the training of the personnel to be entrusted with the expenditure of public health appropriations as was recently emphasized in the conference called under the auspices of Surgeon General Cumming in Washington. It is essential, too, if official public health work is to be effective, that it should be properly correlated with the invaluable activities of the voluntary agencies in the public health field, and that efforts should be made on a more extensive scale to promote widespread public support of the public health movement on the part of the community.

It is to the American Public Health Association that one naturally looks for primary leadership here, and in the past this Association has been more or less active along all the lines indicated. There has been within the Association an increasing feeling of discontent with the results achieved and a growing conviction that more might be accomplished by concentration along a narrower line. The whole question of the policy of the Association is now being considered by a strong committee appointed by President McLaughlin, and it seems possible that the Association may decide to shape its policy along definitely professional lines and to leave to other organizations certain phases of the public health movement with which they are perhaps better fitted to deal. If it were frankly recognized that the American Public Health Association, while admitting all who were interested to a grade of associate membership, should be primarily the official organization of the technical experts of this continent in the field of public health it could exercise a great and beneficent influence in the development of professional *esprit de corps*, and in the formulation and standardization of administrative procedures. An American Public Health Association developed along this line should have state branches which like the parent society were primarily professional in nature.

If this policy should be followed, it would then be desirable to organize more popular public health associations, representing primarily the voluntary agencies, to mobilize public support within each state for the stimulation and support of the official program. If the state tuberculosis organizations which have been developed to such a high degree for a particular purpose could be broadened in their scope, as has been already the case in certain instances, and perhaps placed under the leadership of the National Health Council, we should have an ideal dual organization, insuring on the one hand sound professional standards and on the other enlightened popular support.

The third fundamental question, that of the training of sanitary personnel, must in any case be handled in large measure by the universities; but for the training of workers now in the field, the system of health institutes organized by the United States Public Health Service would seem of distinct promise, and it may be hoped that this system will be continued in the future under its present auspices.

### Then and Now

PROGRESS is relative. Present achievement is fairly to be appraised only through parallel or contrast with that of an earlier period. In the field of medicine, for instance, if modern highly specialized technic is not effectual in improving general health conditions it must be considered that progress is delayed to the extent that sanitary science lags behind surgical skill. Experimentation in the field of public health is replacing the old method of subjecting the whole people to needless risks on a large scale and gambling on survival of the fittest, but how many of the old difficulties in the way of practising the medical arts and sciences have been removed is little appreciated without a comparison of this age with an earlier period.

We have been reading with interest and much enlightenment a book "The American Herbal," which was brought out to "control variations in practice and to give the newer discoveries and improvements in chemistry to American physicians—especially those in country places" by Samuel Stearns in 1801. These issues are with us more than one hundred years later, but are identified with different situations. "Made in America" drugs are urged in this book, and public aid sought for medical publication and education through legislative permission to raise moneys by a lottery, "a privilege often granted to colleges, churches, blacksmiths, and weavers."

That public opinion still fails to support scientific needs is shown in the recent statement from the Educational Board of the Rockefeller Foundation of huge gifts made necessary because "medical schools do not successfully appeal on a large scale to the general public or the individual donor." The dearth of medical publication, however, no longer exists, and there is a marked contrast in the ease with which data may be compiled, for in the preparation of this "Herbal" Stearns was obliged to collect his material by first hand observation and its accumulation required of him "11,607 miles of travel by land and 11,578 by water."

Perhaps an even greater contrast is seen in the conservative claims of present day physicians regarding the curative powers of modern medicine. The 1801 Herbal abounds in positive cures so many and various that choice might be exerted as to whether cure was sought through purging, phlebotomy, or infusion. Specific and absolute cures were not lacking for cancer, consumption, and the bite of a mad dog. Cider was a wholesale preventive medicine, poultices of horseradish were effective in deliriums, and the left hind foot of an elk was highly curative in

epilepsy. Stearns gives minute directions as to the use of a new beverage made from the coffee berry, which was to be boiled from eight to twelve hours before being "drank," and was known to "assist the digestion, promote the natural secretions, prevent sleepiness, and relieve spasmodic asthma." It was likewise recommended for kidney disorders. One hundred years *have* marked progress. Modern pharmacology is at least free from magic, the newer scientific findings find immediate circulation as news, and scientific doubt demands proof positive of "cures." Nor would any medical writer of the present day dare to herald his book by the naïve statement made by this author that his work had brought together "a larger number of new medical discoveries and improvements than was ever collected in any former period of time since the world began."

### The Physician the First Line of Sanitary Defense

IN THE development of the specialty of sanitation, there is a danger that the importance of the practising physician as the first line of sanitary defense may be lost sight of. The physician himself is apt to feel that his connection with sanitary work is remote and that such sanitary duties as he is legally required to perform are an unnecessary hardship, while on the other hand, the sanitarian may assume a self-sufficiency and forgets that in the control of the infections, he is helpless without the intelligent cooperation of the practitioner.

To cite the concrete example of the prevention of the spread of typhoid fever from the infectious patient to the infectible citizen: the health officer administers the mass-protective operations through the work of his bacteriologist who makes the laboratory diagnosis, determines the purity of the water supply by appropriate examinations, and prepares the anti-typhoid vaccine: the health officer carries on the investigation of the source of the disease and the way it has been disseminated and conducts the propaganda for public education: his sanitary engineer administers the water supply, the sewage disposal, and the garbage collection and destruction: his food and milk inspectors insure the purity of these potential vehicles for the *Bacillus typhosus*: the health officer carries out the measures necessary to control carriers. But it is the physician who first sees the sick man, who makes the clinical diagnosis, who supervises the disinfection of the discharges, who instructs and vaccinates the family, who makes the morbidity report and in case of a fatal outcome, the death report.

A good many physicians take their sanitary responsibilities rather lightly and perhaps the reason for this lies in the undergraduate training they have received. It is probably more accurate in the case of the older men to say "the undergraduate training they have *not* received." Undergraduate instruction in hygiene either receives too little stress or the enthusiastic lecturer tries to make sanitarians out of young men whose minds are already turning longingly to some other specialty. As a rule, the hygiene course is regarded by the student body as a bore or a "cinch-course." The average student takes it because he has to and learns the minimum on which to acquire a passing mark. Of course there are exceptions. A skillful teacher can make the course one of almost romantic interest and can impart to the simplest fact a marvelous adhesive quality. Also there are good students whose minds like hungry amebae throw their pseudopodia around every fact. But, unfortunately, such a teacher or such a student is in the words of Horace a "*rara avis in terrae.*"

Undergraduate instruction in hygiene for medical students should be basic, aiming at laying a good groundwork upon which the student may later, by special courses, erect a solid superstructure if he desires to specialize in sanitary medicine. It should be an elementary course, dealing with epidemiology in a broad way rather in minutiae, aiming to give the student a bird's-eye view of the requirements of health rather than a microscopic picture of the prevention of disease. Above all, it should emphasize the public health duties and responsibilities of physicians, so ingraining the lesson that whatsoever specialty may be later adopted as a life work, the fulfillment of these obligations will be automatic. The average young graduate does not know how to make out a death certificate properly; when it comes to deciding between the primary and secondary causes of death, he is often puzzled to make a choice; he dimly knows that he should report births but he is usually unconvinced as to the necessity of so doing, other than in compliance with a law which he unconsciously regards as unjust; the notification of the communicable diseases to him is a nuisance and he considers the reporting of tuberculous and venereal cases as an unwarranted invasion of his privacy.

Yet these things are the first and great public health duties of physicians—they are the messages from the front-line trench upon which the staff in the rear may base the attack—yet the medical colleges which accurately train their students in these simple but vitally important things are few and far between.

While the medical college is the place to begin,

the graduate need not be forgotten. Everything from moral suasion to arrest, fines, and imprisonment has been tried to get practitioners to cooperate in public health work, to secure the minimum assistance which the law requires, but a certain proportion of graduate physicians will not make a report if they can avoid so doing. This is the place for the health officer to educate, first of all the physician himself and next the layman, so that it will be publicly realized that the practitioner who does not make reports is unfaithful to his duty to his patient and to the community, of which he is, after all, the first line of sanitary defense.

### Gratuitous Medical Advice by Amateurs

IT SEEMS strange that medical advice should be so freely given by people who know absolutely nothing about medicine and so credulously received. Why it is that on medical subjects, the layman is so ready to contradict the opinion of a specialist it is rather hard to say. It may be due to the mere fact that on most other subjects the layman knows more than he does of medicine. The definition of an argument that it consists of two persons talking about something of which neither knows anything may to a certain extent explain the condition here.

The habit of giving advice on medical questions as well as the habit of receiving it is much more pernicious than the average person realizes. Numerous instances may be recalled in which temporary or even permanent harm was done because the patient followed some detrimental advice. A case in point occurred recently in an industrial plant. One of the employees swallowed a pin. Rather frightened, he left his work to go up to consult the physician at the plant, when the department manager—a woman of apparently average intelligence—intercepted him and told him he ought to waste no time even to go to a doctor's office but should instead run to the drug store and quickly get a large dose of castor oil. The case followed the usual course of complication from delay and wrong method, but the man eventually recovered. The department manager when severely reprimanded, was at first very indignant and could not understand why she should be scolded, especially as but a few months before a physician gave her baby a dose of castor oil after the baby had swallowed a small marble. She regarded the two instances as parallel and depended on her own experience. The seriousness of her conclusion was fully explained to her and she will probably never again make the same mistake.

If a person were asked for advice concerning a legal tangle or concerning a business problem the advice usually given would be: "That does not look very well—you ought to see a lawyer," or "I would be careful there, you may lose a lot of money. You ought to see so and so, he is in that business." In either case sums of money are at stake which, when compared to a problem of health or life and death are, strange to say, held as relatively unimportant. How often have we heard stories like the following:

"Mrs. Jones told me to put on carbolic vaselin and I didn't know it would do any harm;" or, "Mrs. Smith said that when her baby was burned that the doctor put on some oil and it healed, and I didn't know that the scar would pull little Johnie's arm up so that he couldn't bend it any more."

While we are launching campaigns against cancer, campaigns against goiter, campaigns against infections, etc., it might be apropos to launch a campaign against the readiness of amateurs to give medical advice, perhaps in situations that would tax the judgment of a trained and experienced medical man.

---

### Visual Defects in Schools

THE value of school medical service to the community is nowhere better illustrated than in the care of the eyes of young children, states a recent editorial in the *Lancet*. In Bristol, out of 1,452 children for whom spectacles were prescribed, in only five cases did the children fail to obtain them, but it is pointed out that in the case of squint, which affects 2 per cent of the school population, school inspection comes too late for corrective measures as by the time the child has reached school age in a large proportion of cases the squinting eye has already become amblyopic, and there remains to be devised some effective way of getting squinting children of less than school age under treatment.

It is recommended that for statistical purposes the term "defective vision" be defined. The fact that from Bristol 4.41 school children were reported as having defective vision, while in Kent the number of children affected was reported as 571, indicates a wide difference in standards of examination. When we read that in cases of eyestrain 60 per cent were due to hyperopia and 20 per cent to hyperopic astigmatism, it becomes important to determine the proportion of hyperopia to the total power of accommodation which is considered sufficient to cause eyestrain, and what is the minimum amount of astigmatism in children which calls for correction. School furniture and school lighting come in for their share

of criticism as causing eye disease. Undoubtedly faulty postures favor myopia, as do positions requiring school children to face the source of light.

### Industrial Physicians in Seventh Annual Meeting

THE American Association of Industrial Physicians and Surgeons met in their seventh annual session in St. Louis May 22 and 23. It is interesting to note the progress of this Association from year to year as indicated by the character of its successive meetings. This interest was accentuated in the St. Louis conference in that the past year of greatest business depression was a most severe test as to the stability of industrial medicine.

To those of faint heart the report of the Secretary-Treasurer, showing a gain of approximately one hundred members, with a corresponding decrease in the list of members delinquent in dues, must have been encouraging. The strong position of the Association, as reflected in the report of the year's work, not only reflects great credit upon the officers of the Association but should forever dispel the notion that this new specialty is a war baby, to disappear from view along with many other frills introduced into industry for temporary advantage during that time of stress. On the contrary, the character of the program, the quality and quantity of attendance can suggest but one thing, and that is a progression that is definite and continuous: that in the main Industry has sensed the true values in medical supervision of employees, and that with the return of business prosperity industrial medicine will more and more become an integral part of any well considered program of management.

The luncheon was attended by one hundred prominent business men of St. Louis.

Perhaps the most important object considered was that of the absolute necessity of finding ways and means of financing a full time secretary within the coming months. A fully matured plan of raising the required money will shortly be placed before the membership, but the final responsibility of getting the fund together will fall upon the individual members. A sufficient number of the men present expressed a willingness to appeal to their several corporations and the belief that substantial pledges could be secured for a try-out period covering a year. It was also that general opinion that a full time secretary would so improve the value of the Association to Industry that no difficulty would be found thereafter in securing ample funds for really extensive activities.

## Common Sense in Factory Ventilation

*Primary Aims of Air Conditioning Are  
Air Movement and Avoiding Overheating*

BY C.-E. A. WINSLOW, DR. P.H., PROFESSOR OF PUBLIC HEALTH, YALE SCHOOL OF MEDICINE, CHAIRMAN, NEW YORK STATE COMMISSION ON VENTILATION, NEW HAVEN, CONN.

STUDIES which have been conducted in recent years have gone far to clarify our ideas as to the objectives of ventilation; and it is now universally recognized that the primary physiological aim of air conditioning is to avoid overheating and provide a moderate but not exclusive degree of air movement. In industrial processes which involve the generation of poisonous fumes or dusts and in processes where mineral or metallic dust threatens direct mechanical injury to the lung tissue, the chemical and microscopical characteristics of the atmosphere become of prime importance. The fume and dust problem, however, is a specific one with which the present article does not attempt to deal. In the average factory work room as in the office, school, or auditorium, we are not concerned with oxygen exhaustion or carbon dioxide production which never reach a point where they are physically harmful; nor are we concerned with the presence of hypothetical crowd poison which numerous careful experiments have shown to be a myth. The cause of discomfort in the ordinary badly ventilated room is heat and stagnation combined in many instances with excess humidity, and it is these conditions which we must strive to control if factory life is to be healthful and efficient.

While recent studies have freed us from the fear of certain atmospheric bogies of the past, they have only

served to emphasize more and more clearly the serious harm that is due to the neglect of proper temperature control in occupied rooms. The researches of the New York State Commission on Ventilation in particular have indicated that even a temperature of 75° F. exerts a fundamental influence upon the body temperature, blood pressure, and heart rate, that it substantially reduces efficiency, and that it tends to a material increase in the prevalence of respiratory disease. When we note that under conditions comparable to those which obtain in the ordinary factory the amount of physical work performed in a given time is 15 per cent greater at 68° than at 75° we can realize the vital importance of this problem. Furthermore, in the New York studies the absence due to respiratory disease was increased about 75 per cent in slightly overheated school-room as compared with those maintained at a temperature between 66° and 67°, which indicates the appalling loss to industry due to absenteeism which may be properly chargeable against defective temperature control. A survey of temperature conditions in New York factories some years ago showed that in 215 factory work-rooms, studied in cool weather when the outside temperature was 70° or below, only 59 rooms were at a temperature of 72° or less, 93 at a temperature between 73 and 79° and 63 at a temperature of 80° and over. The loss in

human vitality and productive efficiency due to overheating in the factories of the United States is an almost incalculable one.

The first step in factory ventilation is a definite knowledge of existing conditions. No more important advance was ever taken in schoolroom ventilation than the requirement in New York City that a thermometer should be installed on the front of each teacher's desk with a big red line at 68°. There should be a thermometer installed in every factory work-room and periodic observation of this thermometer should be recognized as an essential part of the duty of the foreman. As the representative of the management he is in direct charge of production and the temperature of the air is a primary factor in productive industry.

When the temperature is found to exceed 68° in the ordinary factory work-room there is a clear indication that something should be done; and nine times out of ten the remedy can be found without elaborate technical investigation but by the application of the ordinary principles of common sense. In a great many, perhaps the majority of instances, the overheating is due not to any lack of essential ventilation provisions but merely to the unintelligent use of heat sources and can be controlled by the turning off of radiation units. Too often the valves are opened in October and never touched again until May, while a mod-

icum of intelligent supervision would not only contribute to health and efficiency but would effect a material saving in the coal bills as well.

If the control of direct and indirect heating is not sufficient by itself to maintain a low temperature, recourse should next be had to the possibilities of window ventilation and in a considerable proportion of factory work-rooms the flushing out of the work-room by opening all the windows before work and during the noon hour, with as much window ventilation as may be possible during the shifts, will secure good working conditions. Where the room is large and crowded it may be necessary to adopt the three devices which have been so useful in school-room ventilation—the location of radiation units beneath the windows to temper the incoming air—the admission of air over slanting window boards to avoid drafts on those near by—and the provision of a gravity exhaust duct for the removal of vitiated room air near the ceiling. Once the principles of this type of ventilation are grasped, its application to a given work-room can be easily made by any competent engineer.

#### Main Points of Air Conditioning

There will always of course remain a certain group of factory work-rooms where the problems of ventilation are more difficult and where expert advice will be required. In very large and very crowded rooms and in rooms where the industrial processes eliminate a large amount of heat or add materially to the humidity of the atmosphere, plenum or exhaust ventilation or both will be required. We have ample experience to show that even very difficult problems can be solved by the ventilating engineers with complete success. Factory work-rooms containing annealing furnaces producing an enormous amount of heat and factory work rooms in which a high temperature is combined with the constant generation of steam can be maintained, during the winter season at least, in perfectly comfortable conditions by properly designed fan ventilation systems. Where systems of this kind are required, however, it is well to call in the best type of expert advice. If plenum ventilation is needed at all, it requires expert design in order to be efficient and the average forced ventilating system designed by plant mechanics is, in my experience, generally worse than useless.

A common sense attempt to promote health and efficiency in the factory

through sound air conditioning involves, therefore, the following main points: (a) installation of thermometers in the factory work rooms and the responsibility of the foreman for a knowledge of the condition which exists; (b) the attempt to maintain temperatures below 68° by the regulation of heat sources and the intelli-

gent manipulation of windows; (c) if these means fail after systematic trial, recourse to a qualified heating and ventilating engineer. The general pursuance of this policy would involve a saving of many days of illness to the industrial worker and of many thousands of dollars to the manufacturers of the United States.

## Remarks on Color Vision

**I**MPORTANT as is the aspect of color vision from the medical practitioner's standpoint, the degree of color blindness which renders a man dangerous to public service is still undetermined and there is no universally recognized standard of rejection for color blindness since the wool test has become obsolete.<sup>1</sup> The whole matter has been reviewed by Captain E. J. Grow, M.C., U.S.N., in a recent issue of *The Military Surgeon*.

Color blindness is found both as an acquired and congenital affection. Congenital color blindness may pre-

blindness may be found; in fact, it is difficult to find two color blind persons with exactly the same amount and degree of color defect. It is also rather unusual to find a person who is completely color blind to one color without at the same time being more or less deficient in the perception of at least one other color.

No one knows with certainty exactly how colors are perceived by the color blind. A person who is red blind sees a dark red object as nearly black, while a light, well saturated red excites in him a visual sensation

Keystone View Company.

Color tests, so great a factor in safety, and so important in estimates of vocational fitness, are still largely optional and are far from being uniform either in standards or practice. The border-line cases often baffle detection. In the test here shown the color perimeter is employed to determine the exact visual fields affected by the defective color vision.

sent a total inability to distinguish any color whatever, a condition very rarely found, or it may show a defect in color perception so slight as to be discovered only with difficulty. Between these two extremes an infinite number of degrees of partial color

1. Grow, Capt. E. J.: Remarks on Color Blindness. Together with Some of the Objections Found with a Few of the Color Perception Tests Now in Use, *Military Surgeon*, November, 1921.

not unlike that received from a light green. In this way a red-blind individual is often confusing certain shades of red and green, but not all shades. It is pointed out by Grow that this tendency to confuse red and green is made the more troublesome in the Navy by the fact that most of the running lights in the Navy have the distinct bluish cast which is so often a confusion color with the red-blind.

Keystone View Company.

No one knows exactly how colors appear to the color blind, but in a general way the acuity of color vision finds an index in the color-mixing test. Both of the discs shown are the same. The one on the left revolves and shows the proportionate admixture of white which gives the impression of gray. This test is made in the paint industry.

The quality of luminosity in a color is very readily utilized by the color blind in distinguishing colors, a fact not to be lost sight of in tests for color blindness.

Acquired color blindness is always met with in cases of optic atrophy, a disease which furnishes one of the most frequent causes of disturbed color vision. Here there is a loss of

visual acuity along with a gradual lessening of the color vision. In this class of cases the loss of central perception for green is first noticed, followed closely by that for red, and by the time these are gone the loss of perception for yellow and, finally, for blue is experienced. In some cases of poisoning by chemicals, also not infrequently with persons who use alcohol and tobacco in excess, there is a small central scotoma for colors. If from these latter causes, color perception is often restored provided the case is properly treated. Almost invariably in acquired color blindness the form vision is also faulty, which affords an aid in diagnosing the acquired from the congenital type.

The chief need, according to Grow, is the "establishment of a point of threshold below which it is not safe to accept men for a given service." Edridge-Green<sup>2</sup> states that "anyone who can distinguish between the red, green, and white lights at a distance of a mile has sufficiently good color perception for the purpose of navigation at sea. He has undertaken to define the degree of defective color perception corresponding to a failure to distinguish between the red, green, and white lights used at sea at a distance of a mile. He considers that about 25 per cent of men have diminished color perception in comparison with the remaining 75 per cent who

<sup>2</sup> Edridge-Green, F. W.: *New Researches in Color Vision*, *Lancet*, Lond., Feb. 25, 1922.

are normal. Only about 5 per cent, however, will fail to distinguish between the red, green, and white lights of a properly constructed lantern or with the actual lights themselves at a distance of a mile. These men will equally fail with other properly constructed tests. These defectives, says Edridge-Green, on examination with the spectrometer, may be ranged in three definite classes: (1) The dichromic, who see only two colors in the spectrum, red and violet; (2) the trichromic, who see only three colors in the spectrum, red, green, and violet, and who designate the yellow of the spectrum as red-green; and (3) those who have shortening of the red end of the spectrum. A person of very acute color vision can distinguish seven colors in the solar spectrum. Those who have for all practical purposes normal color vision see six, five, or four colors.

Defects of light perception are quite distinct from defective color perception, according to Edridge-Green. When the luminosity curve is the same as normal, there is no evidence to show that the perception of white is not the same as normal. He adduces some interesting facts with reference to the effect of fatigue on the appearance of colors, some of which he considers so novel and unexpected that much further research is needed before a definite explanation can be given of the underlying physiological processes of color perception.

## Value of Comparative Records in Industry\*

### Should Standardize Sickness, Accident and Absentee Statistics for Use of All

By ROBERT E. ANDREWS, M.D., LUDLOW MANUFACTURING ASSOCIATES, LUDLOW, MASS.

**I**N attempting to prepare a short paper on the value of keeping records comparable with those of similar industries, the writer finds that there is almost a complete lack of data to which to point as a forceful example and argument. With the exception of the incomplete returns gathered by the Public Health Service and a few scattered publications, the subject seems to have been completely neglected. There seem as yet to be no accepted standards by which the medical departments of two concerns working along similar lines are classifying their risks, their ac-

cidents, their illnesses, their lost time, and industrial hazards.

To collect adequate data useful to others in similar industrial work will call for research. Scattered general surveys of special groups of employees have been carried out, but the facts as determined have little value in comparison with other industries. The motive for carrying out these surveys out has been almost completely selfish, with little or no thought toward the help they might bring to industry in general and their type of industry in particular.

The economic loss to industry through illness and accident has never been accurately determined, but

is reflected directly through absentee records. The lost time, the labor turnover, the expense of training new operatives, the resulting idle machinery, all enter into the total cost of the above. Nobody will deny the necessity for cutting down unnecessary absenteeism, but how many know what is necessary absenteeism, and what is the irreducible minimum?

Standardization of keeping and publishing results is absolutely necessary to make statistics talk, and to get the greatest value from a study of medical problems, it is absolutely essential to compare them with others similarly recorded, but such facts are not at the present time available.

\*Read before the New England Conference of Physicians in Industry, January 7, 1922.

Physicians in industry should endeavor to establish an efficient method of comparison of the tangible results of constructive work.

Statistics as such have no value except through their interpretation. To the narrow minded they are a nuisance, a bother, an expense, something never followed up, and requiring extra clerical help and overtime study. The introduction of the fairly simple equipment necessary has not yet been forced to the attention of industrial physicians, and it is of this equipment that will be treated later.

The following questions are those the solution of which among many others would be readily at hand if comparative records were available:

- (1) How do the hazards of your industry compare with those of other similar concerns?
- (2) What is your per cent of lost time injuries as compared with theirs?
- (3) Have you a healthier working force?
- (4) Are you losing more days out from sickness than they?
- (5) Are your illnesses the same proportionately as theirs?
- (6) Is your percentage of sickness to total absenteeism higher or lower than theirs?
- (7) Are your methods of combating illness and injury giving you better results?
- (8) How does your risk of subnormals on specific jobs compare?
- (9) Have you a greater proportion of members in your organization of the sickly and careless group?
- (10) When you have segregated these most frequently using the clinic, do you find this group too large?
- (11) Is your record better than your competitor's and can you prove it?

The application of a standard method for determining all this has yet to be worked out. A tentative plan has just been developed and instituted by the writer, a description of which will be given later. To accomplish what we wish to know there are certain data which must be available or capable of interpretation through statistics. First, a "lost time illness" classification must be drawn up, preferably according to the "International List of Causes of Death," and next, a classification of lost time accidents. There are two methods of analysis (1) by Holerith punch card, or (2) by a punch card of the "Findex System." The following is a Holerith punch card as devised by the writer to record sicknesses; accident (compensation, non-compensation and outside), both as to types and cause; absenteeism; lost time; etc.

The following codes under their

separate headings were drawn up for the proper punching of the above card. The cards when punched may be sorted as desired for analysis:

**DISEASE CLASSIFICATION**

- (1) Typhoid; (2) influenza and grippe; (3) epidemic smallpox; (4) measles; (5) scarlet fever; (6) whooping cough; (7) diphtheria; (8) mumps; (9) German measles; (10) chicken pox; (11) other epidemics; (12) purulent infections and septicemia; (13) pulmonary tuberculosis; (14) other forms of tuberculosis; (15) cancer, all forms; (16) rheumatism; (17) chronic occupational poisons; (18) other general diseases; (19) mental alienation; (20) neuralgia and neuritis; (21) other diseases of the nervous system; (22) diseases of eyes and adnexa; (23) diseases of ears; (24) diseases of the heart; (25) diseases of veins; (26) other diseases of circulatory system.
- (27) Colds and other diseases of nasal fossae; (28) bronchitis; (29) broncho pneumonia and lobar pneumonia; (30) pleurisy; (31) other diseases of respiratory system; (32) diseases of mouth and adnexa; (33) tonsillitis and other diseases of the pharynx; (34) diseases of the stomach; (35) diarrhoea and enteritis; (36) appendicitis and typhlitis; (37) hernia; (38)

- (43) card back; (44) frame front; (45) frame back; (46) drawing hand; (47) single card; (48) 1½ card; (49) double card; (50) head doffer; (51) doffer; (52) rover; (53) card picker; (54) piecing; (55) spinning; (56) creeling; (57) quilling; (58) weaving webbing; (59) weaving bagging; (60) rolling; (61) polishing; (62) reeling; (63) twisting; (64) tubing.
- (65) Laying; (66) winding; (67) dyeing; (68) bundling; (69) balling; (70) sewing; (71) loading; (72) salt mixing; (73) dresser tender; (74) filling winder; (75) tying in; (76) calender; (77) folder; (78) bag stamper; (79) bag sewer; (80) bag repairer; (81) baler; (82) marker; (83) machinist; (84) blacksmith; (85) welder; (86) steam fitter; (87) pin shop; (88) repair shop; (89) tinsmith; (90) belt shop; (91) carpenter; (92) electrician; (93) painter; (94) power house; (95) engineer; (96) laborer; (97) watchman; (98) store clerk; (99) checker.

**CODE OF NATIONALITY**

- (1) American; (2) Scotch; (3) French; (4) Portuguese; (5) Polish; (6) Italian; (7) English; (8) Irish; (9) German; (10) Indian; (11) Lithuanian; (12) Hungarian; (13) Russian; (14) Greek; (15) Armenian; (16) Bohemian; (17) Belgian; (18) Servian; (19) Syrian; (20) Spanish.

- other diseases of the digestive system; (39) acute nephritis and bright's disease; (40) other genito-urinary diseases, non-venereal; (41) furuncle; (42) other skin diseases; (43) diseases of bones and joints; (44) lumbago and other diseases of organs of locomotion; (45) malformations; (46) affections produced by external causes; (47) ill defined and unclassified diseases; (48) sickness of short disability; (49) venereal disease and complications; (50) gynecological disturbances; (51) pregnancy.

**CODE OF ACCIDENT CAUSES**

- (1) Power engine; (2) power turbine; (3) power motor; (4) power H. T. transmission machinery; (5) power low T. transmission machinery; (6) transmission on jack shaft; (7) transmission countershafts; (8) transmission line shaft; (9) elevator car; (10) elevator machinery; (11) elevator landing; (12) tools, power; (13) tools, power, portable; (14) machinery point of operation; (15) machinery moving parts; (16) fall; (17) falling material; (18) handling; (19) hand tools; (20) electrical; (21) transportation; (22) horse play; (23) bobbins; (24) boxes; (25) floor; (26) striking object; (27) acid; (28) conveyor; (29) occupational; (30) unclassified.

**CODE OF ACCIDENT TYPES**

- (1) Slivers; (2) abrasions; (3) contusions; (4) lacerations; (5) septic cases; (6) strains and sprains; (7) fractures; (8) foreign bodies in eye; (9) boils; (10) burns.

**CODE OF OCCUPATION**

- (1) Overseer; (2) assistant; (3) second hand; (4) clerk; (5) oiler; (6) spare; (7) elevator; (8) weigher; (9) box man; (10) trucker; (11) repairer; (12) cleaning; (13) sweeping; (14) waste and flyings; (15) dust shaker; (16) bin man; (17) belts, bands and rollers; (18) bobbin setter; (19) inspector; (20) lagger; (21) janitor; (22) selecting jute; (23) bagging sorter; (24) starch carrier; (25) slasher tender; (26) loom fixer; (27) cleaning bobbins; (28) ball binding; (29) opener; (30) raw stock piecer.
- (31) Softener feeder; (32) softener catcher; (33) picker tender; (34) emulsion mixer; (35) hatcher; (36) knot chopper; (37) hammer; (38) separator feeder; (39) lapper; (40) spreader; (41) can packer; (42) card front;

**CODE OF SEX STATUS**

- (1) Man, single; (2) man, married; (3) man, widowed; (4) woman, single; (5) woman, married; (6) woman, widowed; (7) divorced man; (8) divorced woman.

**CODE OF ABSENTEEISMS**

- (1) Compensation accident; (2) non compensation accident; (3) outside accident; (4) sickness; (5) sickness in family; (6) excused; (7) unexcused; (8) vacation; (9) needed at home; (10) marriage.

The application of these codes will give among other things:

- (1) Data on lost time from sickness; (2) data on lost time from accidents; (3) facts for analysis of the above by sickness, accident, age, department, sex, martial status, nationality, job, length of service, and day of week and months; (4) data on the frequency of illness and accident among our subnormal risks on specific jobs; (5) seasonal fluctuations of our sickness and injuries; (6) the effect of the social status on our absenteeism; (7) effect of jobs on development of degenerative disease; (8) segregation of our careless and sickly group; (9) progressive reduction of accident and injury from intelligent study of jobs and worker.

The standardization of sickness, accident, and absentee statistics in available form in one's own plant and industry for comparative purposes is a duty every industrial physician should be called upon to sponsor.

# Tuberculosis as an Occupational Disease

## The Factors Primarily Responsible for Lowered Resistance Activate Tuberculosis

By ROBERT THOMAS LEGGE, M.D., F.A.C.S., PROFESSOR OF HYGIENE, UNIVERSITY OF CALIFORNIA, BERKELEY, CAL.

**I**N A recent number of the London *Lancet*, Professor Benjamin Moore, under the title of "Factory Conditions and Phthisis in Great Britain," reports some extensive studies on the effects of the massing together of workmen in factories as distinct from the effects of urban housing, and showed clearly that urban employment conduces to increase the prevalence of phthisis. He states that it is fairly well known that there is more tuberculosis among males than females in cities, and that the reverse is the case in the country. Prior to seventy years ago this condition did not exist, as it is an outcome of modern industry. Up to the age of fourteen or fifteen, coincident with the usual beginning of employment in industry, the mortality of females is 50 per cent greater than that of males. The mortality of both sexes is greater in rural than in urban districts up to the twentieth year, and between the twentieth and thirtieth years this condition is reversed. After the thirtieth year there begins an enormous increase in the death rate among urban males, so that while the death rate from the disease stays nearly at level for rural males, and for rural and city females, the urban males throughout the country die on an average of double this rate and over.

Further proof that the cause of this higher mortality among urban males is due to working and not to housing conditions, is found in the fact that up to the twentieth year both urban and rural males are healthier than females, and in the case of both sexes, urban dwellers are healthier than rural.

Deaths from phthisis among printers, cutlers, grinders, quartz workers, and file makers follow the same upward trend as those among urban males, and observations in factories of conditions of work, seem to fix these working conditions as the true cause of the trouble. How noticeable are these facts when we note that the girl who remains at home and the professional man or laborer in and out of doors industrial pursuit, are comparatively immune from tuberculosis, whereas the sister or brother in

*Tuberculosis may well be considered an occupational disease when medical supervision with periodical physical examination are not provided, and when remedy is not sought for such industrial health hazards as dust, dampness, devitalized air, darkness, fatigue, unsafe temperatures, and avoidable poisons and infections.*

*That Industry is sensing this responsibility is attested by the application in industry of the principles of public health nursing, supplemented of late by specific attention to such defects in the nutrition of workers as can be laid at the door of wage or working conditions.*

the mill, factory or office falls a victim to the disease.

### Many Concurrent Factors

Tuberculosis in industrial employments usually follows after a long period of exposure to debilitating conditions. The factors that are primarily responsible are overstrain, unhealthy surroundings, and close contact with operators already infected with the disease. As Hoffman has clearly proved in his "Statistics of Mortality" dust in the dusty trades plays the important rôle as the principal factor. It makes very little difference as to what kind of dust the artisan has been exposed: whether metallic, mineral, vegetable or animal. True, some are worse than others, but any dust that is disseminated in the atmosphere and inhaled by the workers, will sooner or later impair the respiratory organs, and produce a favorable nidus for the active development of the disease.

Such a hazard not only lowers the production of the antibodies that would have been resistant to the disease had the worker been employed in a more favorable environment, but it also is responsible for lighting up arrested conditions that may antedate his employment. Even accepting the modern conception that tuberculosis is a social disease, that approximately

85 per cent of the human stock have had some evidence of the infection, and that the disease is contracted in infancy by direct contact and infected milk, medical sociologists, public health officials, and industrial physicians must recognize that unfavorable industrial agencies play the important rôle in re-activation of morbidity in tuberculosis and its greater mortality.

Other contributing factors that must not be lost sight of in industry, and which can be safely labeled occupational hazards, are the dangerous irritating and toxic fumes, excessive humidity, coupled with dampness, extreme heat, cold, and darkness, which tend to reduce the forces of the body. Fatigue due to strain and overwork and alcoholism increases the likelihood of infection as the resistance is lowered under the conditions. Faulty posture, overcrowding, poor ventilation, improper food, and lack of proper rest all figure in the etiology of tuberculosis as an occupational disease.

Pneumonokoniosis is a chronic interstitial pneumonia accompanied by a deposit of pigment due to different forms of dust encountered under conditions of employment. The physical characters of the dust are the important factors in the morbidity and mortality of the disease. In the case of coal miners, anthracosis is not so dangerous as in the case of quartz miners or stone grinders (silicosis) on account of the angulated sharp particles of dust which are more irritating to the ciliated mucosa of the bronchial tract and therefore increase a greater phagocytosis. These particles of dust are carried by the phagocytic epithelial cells to the lymphatics, the bronchial glands, and the finer framework of the lung cells where they are deposited. Recent research on the phagocytosis of quartz *vs.* carbon, showed that the latter is ingested about four times more readily. Mortality statistics now available show that the death rate from tuberculosis in the dusty trades is four times greater than in the population as a whole. Again let it be clearly understood that adult tuberculosis seems only possible when damaged lung tis-

sues receive a constant infection through the air, and the worker is thereby shorn of his resistance and the arrested process is reactivated; for 90 per cent of the industrial workers have received their infections during infancy and early childhood, when the disease is highly communicable and the tissues more vulnerable.

The relationship of tuberculosis to occupational disease is definite and of great importance. It is obvious in consideration of the facts stated, that occupation is pre-eminently at fault, but in determining such a responsibility a careful history of personal and home conditions is necessary, *i.e.*, a recent influenza or pneumonia history, housing, alcoholism, food, clothing and other agencies that would render the worker an easy prey to tuberculosis.

Armstrong has concluded that the Framingham experiment in community health and tuberculosis demonstration holds an important relationship to industrial medicine, and proves definitely what any community can accomplish through the agency of proper medical and public health machinery—1 per cent of the population is suffering from tuberculosis and there are nine or ten active cases to every annual death from the disease. The average community does not report more than 55 per cent of its active cases which was raised 85 per cent at Framingham, and the institutionalization of acute cases was raised from 13 per cent to 42 per cent. Adequate community health work of this kind increased the health budget from forty cents to two dollars *per capita*. But note what was accomplished towards tuberculosis control and mortality: the average tuberculosis mortality for the ten years prior to the demonstration was 121 per 100,000; in 1920 it was cut in half and in 1921 to about one fourth.

Education is the greatest weapon society possesses in the prevention of tuberculosis. The secret of success is teaching in an elementary manner to the women of the home, the necessity of living hygienic lives, the great benefits of fresh air, sunshine, rest, cleanliness, better food and the use of pasteurized milk. And it should be particularly emphasized that tuberculosis is a highly infectious disease in infants and young children, and how essential it is to keep sufferers of active cases of tuberculosis from their presence. The separation of the sick from the well is the modern outcome of the preventorium and sanitarium. The danger of spitting is a national byword, the result of "advertising." Arrest the tubercle bacilli

and spare the child is a slogan for a universal anti-tuberculosis campaign.

It is reputed that 10 per cent of the milk supplied in large cities is infected with tuberculosis. If this is the case, then there should be a law enforced to the effect that only pasteurized milk and butter be offered for sale.

How are the disasters caused by ignorance of the correct conditions of living and working to be brought home to the women who are the future mothers of men? This is answered by educational methods of the public health nurse. This new institution is the last link in the chain of public health activities. The public health nurse is a friendly advisor, a teacher in health education, a social worker and one who can be practical whenever the emergency arises. Her function is to be in the home, not as a "gum shoe" officer, but as a health friend and counselor. Happy will be the day when every precinct will have a public health nurse who has made a survey of her district and knows of every freeholder therein. Then tuberculosis and infectious diseases will be so checked that their existence will be a rarity and the fifty-thousand workers who die of consumption yearly will be living as an asset to the community.

One of the modern advancements made in recent years is the extension of nutrition work into industry. While it is true that the cafeterias were built not from philanthropic motives, but for a strictly business consideration, nevertheless they have proved to serve as a health factor. The industrial manager has been cognizant of the ill effects of the indigestible, old-time, free lunch and the poorly balanced and cold diet of the dinner pail. The direct and indirect advantages are noted in a marked improvement of the health of the worker; less illness, less absences, less alcoholism, increased efficiency and output, and time saving, greater contentment, and better relaxation for recreation, and lastly, better midday ventilation of the workshop. It is readily seen that the benefits derived from an industrial restaurant have a direct influence in lessening tuberculosis by better, clean, wholesome food, properly prepared, the relief of fatigue by relaxation, and the change of air. Minimum wage, like the raising and lowering of the window sash, determines the fall of the tuberculosis rate. No one can work without health, which depends largely upon food, shelter, and relaxation. The solution of this great economical

problem is fundamentally the solution of the eradication of the great white plague.

The public health center, like the dispensary, will evolve into a greater and more adequate service for community needs and requirements. It represents an advanced mile post in community medicine and constitutes the salvation of the tuberculous patient in industry, for it has the advantages of consolidating preventive and curative medicine, and of rendering to the community health, education, social, hospital and dispensary services.

In the present daylight of knowledge, tuberculosis as an occupational disease must be saddled upon the employer, when medical supervision, with periodical physical examinations, is not prescribed, and when such industrial health hazards as dust, dampness, devitalized air, darkness, fatigue, unsafe temperatures, avoidable poisons and infections are disregarded. Industrial responsibility is not ended with providing mechanical exhaust, heating, and ventilating apparatus, a pure water supply and the various modern sanitary measures, such as cuspidors, toilet and wash room necessities. The employer likewise has a paternalistic obligation in offering his employees the advantages of a modern cafeteria, recreational activities, and the application of public health nursing in the home of his artisans. His reward will be demonstrated on the credit side of the ledger by better efficiency, fewer absences, and labor turnover, reduced taxation, and the satisfying knowledge that the reaper of the Great White Plague has been foiled in his path.

Of the 185 cases of occupational diseases reported to the Ohio State Industrial Commission since the section of the Workmen's Compensation Act covering this class of disability became operative last August, a large proportion were due to dermatitis, there being 113 cases of this. Lead poisoning was next with 34; anilin poisoning 3; carbon dioxide 3; anthrax, arsenic, and zinc poisoning, 1 each. Nineteen cases attributed to rheumatism and similar ailments have been disallowed as occupational disease claims.

Dr. W. G. Smillie, the director of the Institute of Hygiene of the Medical School of São Paulo, has instituted a graduate course in public health for physicians engaged in sanitary work.

# Cooperation Keynote of Fatigue Elimination\*

## Committee Aims to Force Realization of Loss and Waste Caused by Fatigue

BY FRANK B. GILBRETH, LL.D., CHAIRMAN, INTERNATIONAL COMMITTEE FOR THE ELIMINATION OF FATIGUE IN INDUSTRY OF THE SOCIETY OF INDUSTRIAL ENGINEERS, MONTCLAIR, N. J.

THE most important development in waste elimination during the past six months has been along the lines of closer cooperation with other bodies interested in allied lines of work. The Eye Sight Conservation Council of America, of which the eminent past president of the Society of Industrial Engineers, Mr. L. W. Wallace, is president, realizing the close affiliation between their work and that of the International Committee for Elimination of Fatigue in Industry, invited the chairman in February to deliver a paper on Eye Conservation in the Industries. This paper dealt with the subject of fatigue, and as a mark of appreciation of the importance of fatigue investigation, the Council is now reprinting the paper as a separate pamphlet in order to arouse interest among its members in the subject of fatigue as it directly concerns the eyes.

The National Safety Council is issuing a book on "Practical Methods for Reducing Fatigue" and has asked for the cooperation of the Committee in this work. The chairman and the business manager of the Society of Industrial Engineers have forwarded such material as available to those in charge of this work.

The American Posture League continues to cooperate most fully, having representatives of the League on the Committee and including representatives of the Committee upon its advisory committee. In this way, reduplication of effort is prevented and closer cooperation assured.

New members of the Committee are, notably, Dr. Louis I. Harris of the department of health of the City of New York, Dr. Tech Petr Ruzek of the Psychotechnic Institute of Masaryks Academie of Labor, and Dr. Ing Stan Spacek of the Czecho-Slovakia Legation at Washington, all of whom are deeply interested in the subject and can wield an enormous interest in the fields of fatigue elimination.

The general emphasis on the elimination of fatigue to be seen in ad-

vertising everywhere we believe is largely the result of our fatigue elimination campaign.

Recommendations for future development focalize interest on two points—first, the necessity for increasing the number of members on the Committee and thus broadening the field of influence. As has been before indicated, we should have a representative in every university and college in the country, in every sister society, in every field of industry. The American Society of Mechanical Engineers has appointed Professor George H. Shephard of Purdue University chairman of a sub-committee of the management division of that Society to represent it on the fatigue committee of this Society. He has appointed the members of his Committee to cooperate with us. It is desired that a representative from every society and college interested in waste elimination become a member.

### Fatigue Movement Abroad

The second important point which is vital at this time is that fatigue elimination should be seriously considered in all efforts towards standardization now going on throughout the world. The chairman has during the last months visited England, Holland, Germany, and Czecho-Slovakia and has been in touch with those at the head of standardization work in other European countries and also in our own country.

At the request of Mr. Spacek, Technical Advisor to Mr. Stepanek, minister of Czecho-Slovakia, the chairman visited Prague in Czecho-Slovakia and, as a result, secured Dr. Ruzek, the eminent director of the Institute of Labor, as a member of the fatigue committee. The purposes of the fatigue elimination committee were explained to Dr. T. G. Masaryk, the President of the Republic, who is vitally interested in all undertakings for the improvement of conditions that make for more comfort and more efficiency of the worker. The chairman also conferred not only with President Klir but with representative members of the Institute Masaryk, that most remarkable cooperative undertaking

where all those interested in industry from every standpoint confer on industrial problems and outline solutions which must prove adequate because they have the approval and enlist the cooperation of all.

Progress in all countries along lines of standardization of material and equipment and along publication and acceptance of specifications is most satisfactory. There is, however, both abroad and in this country a great lack of standardization of practice. Perhaps this standardization may be looked for in the work of the new Division of Simplified Practice of the Department of Commerce which is just outlined and undertaking its work.

If waste elimination in the field of fatigue is to make greatest progress, it is essential that those engaged in this work become acquainted with and interested in the work of the Committee and include fatigue elimination standards among the other standards to be set down. In our report of October 7, 1921, we urged the establishment of such fatigue elimination standards. This is a natural work for the Committee to undertake. However, if we wish best to cooperate with others engaged in standardization, we must bring the subject of fatigue elimination immediately to their attention, in order to insure that all research bodies have this in mind in making their investigations, and that the forthcoming standards of practice, which are essential to development and imperative at this time, may cover the subject of fatigue.

The Committee proposes to bring to the attention of the entire world the unnecessary discomfort, discontent, ill health, inefficiency, loss of production, and all other kinds of wastes that result from unnecessary fatigue. The loss in productivity alone is more than 20 cents a day for each. The correctness of this sum is admitted by all students of economics and industrial engineering. When multiplied by 300 days a year and 40,000,000 workers, the loss competes in amount with the financial debt of our allies to us, and will, incidentally, be much easier to collect.

\*Progress report read before American Society of Industrial Engineers, Detroit, Mich., April, 1922.

# A Work Chair Embodying Comfort and Utility

THE problem of sitting posture is an individual health problem which easily becomes an industrial one when the bodily ills, discomfort, and inefficiency of a large number of employees are found to be dependent on inadequate seating facilities. A work chair which embodies comfort, utility, simplicity in construction, and low cost is described by two articles, one in *Safety* by Arthur B. Emmons, 2nd., M.D., Director Harvard Mercantile Health Work, and the second of which Dr. Emmons is co-author with Joel E. Goldthwait, M.D., orthopedic surgeon of Boston, in the *Journal of Industrial Hygiene*.

To meet the requirements of bodily support, that is, that the weight of the body should be supported by a seat directly under the body and not at the mid-thigh, and that the small of the back should be properly supported, the work chair was designed. It possesses a shallow seat and a back curved forward to fit the small of the back, and is of rigid construction in order to give support and steadiness. This chair has proved to be a generally useful work chair and considerable search has failed to discover any other which approaches it in essential requirements. Adjustable chairs may still be necessary for special work, such as that of the telephone switchboard operator, but adjustability is not an unmixed good.

It nearly always results in unsteadiness and the chair is rarely correctly adjusted to the individual. Moreover, adjustability requires frequent repairs and results in a short-lived chair.

The work chair was especially designed by a committee composed of Dr. Joel E. Goldthwait, chairman, Dr. Lloyd T. Brown, and Mr. Ford, of Massachusetts Institute of Technology, to meet the needs of a large technical education institution. It has proved entirely satisfactory when used at a table or desk. Another similar chair, with arm rest added, was constructed for ordinary class room or lecture work. The sturdy construction of the chair is testified to by the fact that several hundred have been in constant use for five years and are reported to have received no repairs. Inspection of them at the present time shows that the glue has given way and needs replacement in about one in five to ten chairs; otherwise the chairs are in good condition.

The chair has had industrial use in a large clothing factory where many machines are used at tables. The personnel director of this establishment reports as follows:

We have found that the four different heights of the chair (17", 18", 19", 20") we use have been sufficient for all but one or two exceptional cases. The chair has worn very well indeed and is giving great satisfaction to the workers. As for its preventing fatigue, I cannot furnish statistics on this matter, but I do know that any chair which supports the back as this one does and which does not interfere with circulation must have a great deal to do with reducing the fatigue of our workers. I have used this chair myself ever since we first introduced it in the factory, and I wouldn't use any other as a desk chair. I feel that it has helped me to maintain correct posture, and that I am very much more comfortable in it than in any chair I have used as a work chair.

A survey of the twenty-five stores subscribing to the Harvard Mercantile work shows that one of the most glaring examples of bad sitting posture is usually seen in the alteration room where women on kitchen chairs bend over work placed on their knees. Marking rooms disclose many girls

sitting on stools, benches, or discarded chairs manifestly furnishing neither support or comfort. In the main office stenographers sit on adjustable chairs not adjusted. Oftentimes the leather cushion is raised to the height of the stenographer's shoulders rather than supporting the small of the back. High, backless stools at old-fashioned ledged desks are no longer excusable for suitable chairs with backs and footrests will make a good working arrangement. The deep swiveled arm chair at the executive's desk results in compression of the abdomen when he leans over his desk. Thus it is seen that the chairs used in many phases of mercantile work encourage the bending from the waist rather than the hips and offer little support. The faults are obvious, the mechanics simple. The remedy is not applied usually because of lack of attention, and because no one is responsible for their correction.

Another aid to correct posture in office is the sloping desk, which now has been discarded to a large extent. A slight slope prevents considerable

The fool-proof "work chair" showing dimensions.

The work chair.

Correct working posture on the work-chair.

chair. Usually it may be attached to the desk or table. (4) The light coming over the left shoulder is best for general work. Avoid light from directly in front which reflects glare from the work, and also light from the right which casts the shadow of the hand on the work. Light from above is also excellent, especially if reflected from the ceiling, as in totally indirect lighting.

"One chair manufacturer told me," says Dr. Emmons, "that his system of doing business was to learn how many chairs of each kind were sold during the past year and then to make a proportional

Correct resting posture in the work chair.

unnecessary forward bending.

Experience shows that in store work probably between 80 and 90 per cent of the people can be well adapted to their work with the "work chair." This chair, not being adjustable, is foolproof—a very necessary quality. In most stores little thought and less careful planning has been spent on correct seating, and observations in industry disclose the same condition. It is believed, however, that use of a simple foolproof chair is a first step in the right direction.

It has been suggested that the Training Department, with the approval of the physician, adjust to working conditions each new worker and each one transferred. The establishment of such a system is believed to be the most important step in correct mercantile and industrial seating.

To guide the Training Department in this adjustment of the worker to his work the following rules are suggested. (1) Start with the height of desk (usually 30 inches) or table. (2) Subtract the *sitting height* of the individual from his desk height to determine the height of the work chair seat. This may best be done by trying the worker in chairs of different height. (3) If the feet do not rest comfortably on the floor without the thighs resting heavily on the front of the chair seat, provide a foot rest or brace. Rarely is a foot rest satisfactory if attached to the

number of each of those kinds for the present year's business. Thus the faults of traditional seating are perpetuated all about us. The greatest change of breaking this tradition is through the industrial physician who is responsible for the health of a large group, whose technical training enables him to form his own judgments and whose administrative power enables him to carry through his conviction into correct seating."

### The Posture of the Worker

ONE of the leading factors contributing to fatigue in industry is conceded to be the posture of the worker, the question of posture resolving itself into the way the worker sits at his machine as an operator, or works at the table as a finisher, or stands at the pressing board as a presser, states Theresa Wolfson in reporting through the pages of *The Survey* on an intensive campaign for improvement of posture in the Ladies' garment shops in New York City. The Joint Board of Sanitary Control of the industry has nearly complete the results of a study of two hundred representative shops.

As long ago as 1915, Dr. J. W. Scherewschewsky of the United States Public Health Service presented definite facts concerning the diseases of the garment worker attributable to bad posture; yet of the eighty-five

thousand workers in the trade, few have had their postural defects rectified, or have benefited at all by the recommendations made in this study. The present survey has maintained constant contact with the workers in the shops and has brought out the seriousness of improper seating, poor illumination, and bad ventilation, as well as the importance of shop sanitation.

By its presentation of the special problems of posture as applied to the operator, the finisher, and the presser and of remedies which are possible through forethought and a small expenditure the Joint Board of Sanitary Control hopes to create an intelligent understanding of the seating problem in industry. It is not to be wondered at that the faulty seating promotes drooping shoulders, interference with the proper functions of the lungs, hernia, weakened abdominal muscles, and flat feet. Bad posture means fatigue and fatigue means inefficiency. A part of the program aims to bring out the fact that it is a matter of good business on the part of the manufacturer to secure good illumination and comfortable seats for the workers.

In addition to the "List of Publications" issued by the International Labor Office, the Industrial Health Section will issue at regular intervals lists containing information dealing with industrial hygiene.

# The Year's Progress in the Reduction of Noise\*

## Low's Audiometer Aids in Determining Standard Limit of Permissible Noise

By PROF. HENRY J. SPOONER, M.I.MECH.E., F.G.S., ETC., MEMBER OF THE INTERNATIONAL COMMITTEE OF INDUSTRIAL FATIGUE, DIRECTOR OF THE POLYTECHNIC SCHOOL OF ENGINEERING, LONDON, ENGLAND

THE progress of the reduction of noise has been marked in the past year by the interest taken by the public press in the subject, by observation of Fatigue Elimination Day in schools and colleges, and by the devising of instruments with which to measure noise.

Not only has the technical press devoted space and argument to the reduction of noise, notable articles appearing in *The Lancet* and *The Engineer*, but the lay newspapers, among them *The London Times* and the *London Evening News*, have lent their influence to the movement.

On December 5, the fifth annual Fatigue Elimination Day was celebrated. Students submitted essays on fatigue elimination, typical extracts from which are set forth here showing how engineering colleges may usefully cooperate in forwarding the movement.

### Students' Essays on Noise

(1) "The word 'noise' is, in all probability, derived from the Latin 'noxa'—hurt, 'nocere' to hurt. Whoever introduced the word noise into our language must certainly have had a sounder knowledge of acoustics than many business men and engineers of today. It is a great loss to the industry of this country that so few of our manufacturers, judging from recent visits to works, fully grasp the fact that noise affects and, within limits, hurts any workers within appreciable range of its occurrence."

(2) "The effects of noises on the health of the average person vary according to the type of noise. Persistent hammering, such as occurs in a boiler shop, will in time produce partial deafness, as will also the continuous roar of the traffic in a big city. Intermittent knocking if kept up long enough will produce a state of nervous tension bordering on collapse. The distinction between continuous and intermittent noise is seen in the case of a designer or calculator who

can work next to a machine shop and get so used to the whirl of machinery as to become practically oblivious to it, but if the same man were, for example, transferred to a room where a great deal of talking and whistling were going on, his plight would be pitiable. In the latter case, the effort required for him to concentrate on his work, very quickly produces a state of great mental fatigue, or reduces him to a state of great irritability."

(3) "The chief causes of noise in aircraft are: (a) engines; (b) propeller; and (c) external wires. (a) *Engines*.—To eliminate the noise from these, I suggest that they be enclosed in a sound-proof department, the proofing being interlined with some fire-resisting substance. In the bigger types the exhausts might be used to generate heat for the comfort of pilot and passengers at high altitudes. (b) *Propellers*.—I suggest for these a highly efficient low-speed high-pitched propeller coupled to a geared down engine, and a coned centre to prevent whistling of securing bolts. (c) *External Bracing Wires*.—Eliminate the cause, i. e., use no wires but small drawn-steel tubes, or better, use cantilever wings. For under carriages, centre sections, etc., use steel tubes with stream lined fairings."

(4) "Although most noises are detrimental to efficiency there are occasions on which noise serves an extremely useful purpose. A past acquaintance of mine previous to the war was an engineer in charge of a power house which provided power for a small township in British Columbia. As the finances of the concern only permitted the services of one man, he frequently had to sleep in the engine room. In time he became so inured to the sound of his machinery that he could sleep quite comfortably in the engine room, but, if the slightest irregularity in the noise occurred, it aroused him instantly, and he was easily able to remedy any defect which he was able to locate by means of an unusual sound.

In concluding my Chadwick lecture in November last year, I ventured to

suggest that there should be a standard limit of permissible noise beyond which it should be considered a public nuisance. Before this could be practicable, an instrument must be available for measuring noise. Professor A. M. Low, D. Sc., has so improved his audiometer that apparently it goes a long way in the direction of solving the problem. The following is a brief description of it supplied by Professor Low:

The instrument itself consists in the main of four different components: (1) a sound horn; (2) a diaphragm; (3) a mirror; (4) a photographic recording chart; (5) an electric damping device; (6) the new low vibrometer. The mirror is connected to the diaphragm in such a manner that the smallest vibration of the diaphragm produces a corresponding deflection of the mirror, which in its turn causes a spot of light, the source of which is a powerful electric bulb, to be moved to a lesser or a greater extent upon a piece of sensitive photographic paper. This paper is, in its turn, simultaneously moving in the direction at right angles to the direction of the oscillation of light, and the result, when the paper is developed, is an undulating curve traced by the spot of light and varying according to the nature and intensity of the sound which it is desired to register.

In the case of an apparatus fitted with the photographic attachment, the paper is automatically developed in the tank under the machine. In the case of an instrument not fitted with this attachment, a ground glass screen enables the spot of light to be watched by the eye, a scale upon the screen demonstrating clearly the maximum deflection of the spot.

By means of a rotating mirror, part of the wave can be examined before the record is taken photographically. The apparatus is so arranged that the development of the negatives takes place automatically and the sensitised paper is drawn from the instrument carrying the record without any skill being necessary. A particularly important part of the scheme is that the apparatus can be fitted with a syn-

\*Report on the progress of the movement for the reduction of noise read at the spring convention of the American Society of Industrial Engineers at Detroit, Mich., April, 1922.

chronously operating valve for use in research work, in order to expose the diaphragm for a predetermined period; any particular note being recurrently produced.

The importance of such an instrument for use in the scientific production of any form of machinery that is to be silent-running is obvious, as it is absolutely essential that the various sounds produced should be recorded and analyzed. They form practically the only means available for detecting the cause of the trouble, the detection of which at present is more or less a matter of guesswork.

### The New Low Vibrometer

The new low vibrometer has been devised principally for the purpose of effecting comparison between good and bad springing of motor vehicles and of the vibrations caused by the machinery. The new form of the instrument is extremely simple and enables the operator to obtain an exact comparison, not only between the comfort of two different cars, but also between the amount of vibration produced by different crankshafts or by reciprocating parts.

The vibrometer consists mainly of a drum operated by an ordinary clockwork governed motor. Against this drum rests a small glass stylus fed from an inkwell and attached to the end of a spring which is weighted to a different periodicity. The contact of the pen against the paper is regulated by a roller three-sixteenths of an inch in diameter, and the period of the spring can also be varied by altering this to the effective length. This is arranged by sliding the point of support, all the operations being controlled by means of suitably arranged thumb screws. The whole apparatus is enclosed in a glass case which can be lifted off for replacing the paper on the drum in a few moments.

In use, a datum line is made by allowing the drum to revolve before the apparatus is put on the vibrating engine bed, or side car, as the case may be, and the drum is then set to make one complete revolution. The pen can be traversed across the chart if necessary in order to increase the length of the trial.

By means of the vibrometer, not only can the displacement of a car body or railway coach be measured, but the rate of acceleration vertically produced by the bump can be worked out without any complicated gyroscopic apparatus.

For very sensitive work a photographic and damped apparatus of this type is essential, as also for the study

of high speed vibration, as it can be conveniently used in conjunction with a synchronous cinematograph, but for ordinary comparisons between the comfort of cars and the amount of engine vibration produced, the vibrometer in its most simple form is sufficiently accurate.

### Laws Relating to Noise

I do not know how a public or common nuisance is defined in American law, but in English law it is such that it appears hardly to embrace noise. On the other hand, in English law, a private nuisance, is "an act or omission which causes inconvenience or damage to a private person." So we may assume that anyone annoyed or inconvenienced by objectionable noise can call upon the local medical officer of health to take action to get relief. Probably the laws relating to public or common nuisances in both countries will have to be modified to embrace noise unmistakably before any sensible relief from its damaging and wasteful effects can be hoped for.

The fact that the ordinary healthy public finds that a certain amount of noise has a stimulating effect probably explains why our noisy road and rail traffic has been allowed to become such a great nuisance in all our large towns and cities, but, after all, the engineers concerned are to blame, as noise caused directly or indirectly by machinery denotes bad engineering and waste. Until it is more generally recognized that all noises mean loss of energy in some form, we are not likely to get much relief from the intolerable and injurious nuisance. Indeed, it can safely be submitted that the appalling noise of the machinery of our electric trains and trams in particular is a disgrace to a great profession and should not be allowed to continue. These remarks also apply to a large proportion of the motor vehicles, particularly the commercial ones, running on our roads and loudly calling for the attention of the engineering pathologist.

Trouble is usually due to some form of unbalanced movement which is sure to cause noise at high speeds. Faulty gears and worn bearings are also sure to be noisy. But every chief designer worth his salt can devise machinery for almost any purpose that will be practically silent, if he pays attention to such matters and makes the best use of the advances that have been made in workshop practice and processes in recent years, helical gears, and spiral bevel gears, etc., which, if mounted on shafts of sufficient stiffness, are silent running.

In modern practice, the watchwords should be: (1) scientific design from the standpoint of noise, substituting pressure for impact wherever practicable, remembering that the hall-mark of good design is silent running; (2) accurate construction, and efficient lubrication; (3) observant efficient maintenance on the principle that "a stitch in time saves nine."

In looking back upon the gradual evolution of things that matter, I venture to believe that good, if slow, progress has been made in the cause of waste reduction in this, perhaps its most important aspect since the Spring Convention in Milwaukee of April, 1921, and I am full of hope for future developments.

### Gas Masks for Crude Oil Vapors

The Bureau of Mines usually recommends the hose mask for protection against vapors of crude oil. This consists of a Tissot type face-piece that allows breathing through the nose, attached to a non-collapsible rubber hose extending to pure air. Such a mask is very useful in tanks where distances from fresh air are short, but would have limited service in mines. A man can breathe through 100 to 125 feet of hose without undue exertion; with longer lengths it is necessary to force the air to him. Gas masks of the army type having canisters filled with activated charcoal give protection for short periods of time, 5 to 10 minutes, against oil vapors not exceeding 1 or 2 per cent in air. The gas mask is essentially a filter for air containing small admixtures of irrespirable gases, but otherwise normal. Unless it is positively known that the concentrations of vapors do not exceed 2 per cent, gas masks must not be used. Self-contained oxygen breathing apparatus having breathing bags of thin rubberized fabric may be used for periods up to ten minutes in high concentrations of vapors, but thereafter gasoline and petroleum vapors penetrate the rubber. Breathing apparatus made with heavy rubber breathing bags 1/16 inch or more in thickness may be used for periods up to two hours. After use, the breathing bags should be aired in fresh air for at least six hours to rid them of absorbed vapors before further use. The Bureau of Mines is now developing breathing apparatus in which the bag consists of a material impervious to petroleum vapors.

# Efficiency Applied to the Efficiency Expert

## Man of Affairs Often Errs by Not Applying Health Rules to Own Life

BY P. K. HOLMES, M.D., DEPARTMENT OF HYGIENE AND PUBLIC HEALTH, UNIVERSITY OF KENTUCKY, LEXINGTON, KY.

**E**FFICIENCY is the magic word today caught up by every tongue. It is used most frequently and effectively in the business and industrial world. The head of the great business concern has to conduct the affairs of his great concern along approved lines of efficiency. There must be centralization of control; union to facilitate advantageous buying; stimulation toward increased production; methods for utilization of by-products; constant improvement in the quality and quantity of goods turned out; lessening of waste; elimination of useless and time-consuming steps and muscular efforts; the application of scientifically worked out rest periods to increase production and decrease fatigue; shortening of hours and increase of pay to make employees more contented; the introduction of safety devices; and many other things for the sake of efficiency.

The whole keynote here is production,—efficiency. The vision is focused only upon the product that is turned out, the "thing," and in the final analysis the money which the "thing" represents. In order to increase production, mental and physical efficiency on the part of the employee must incidentally be increased.

The conception of such a well organized plan of efficient production and the capacity for putting it into operation comes from the master mind only. It is almost unbelievable to think that the master mind that conceives of high standards of efficiency fails completely to apply the same principles to the body containing the brain which initiated the original idea. In other words, our men of big business fail at the crucial point and apply the principles to the creation and not to the creator. It is safe to say that if our busy business men applied these principles to themselves they would be able through better health to plan even more efficiently for others.

This plan of business efficiency will not permit of men who have to operate delicate and expensive machinery becoming incapacitated through the effects of alcohol poisoning. Quite

*There is much talk of keeping the employees of an industry efficient. To this end they are enjoined to lead a normal healthful life. The wise employer realizes that dependence on artificial stimulants by his working force, late hours, and mis-spent recreation time diminish their labor output.*

*But while urging health habits upon his employees, the captain of industry often flagrantly violates all of them. Narcotics and stimulants, late hours, over-work, and little or no exercise, make him old before his time and he becomes a prey to degenerative disease. The efficiency expert who would apply to others principles of longevity would do well to follow them himself.*

a few heads of business concerns today are refusing to employ men or boys who use tobacco because indications point to a probable loss of working efficiency as a result of its use. It is probable that the person who largely depends upon coffee as an artificial stimulant to carry him through his day's work is placing himself on a lower level of efficiency. The man with weak flabby muscles and shortness of wind cannot long meet the demands of manual labor. The man who is being continually poisoned as a result of chronic constipation which results in loss of mental keenness and physical endurance cannot efficiently sell the products created by the concern which employs him. The man who, through keeping late hours, over-indulgence in aimless amusement, excessive stimulation of the emotions, overdraws upon his bank account of nervous force and is thus incapacitated for doing his best.

These are some of the fundamental principles of business efficiency and repeated disregard of them by the employee means eventual loss of his position. But who is going to dis-

charge the employer himself for falling below the standards of efficiency which he has set up for others? There is nobody to tell him directly that he will lose his "job" if he does not obey the "rules," but his business competitors, who sometimes will get this new conception, will force him out of his "job" in the keen struggle for business supremacy.

The average business man is probably not as clear a thinker and as enduring a worker by virtue of his natural endowments and observance of the laws of health as the average man he employs. The average man of big business does not have time to live according to the laws of health. Theoretically he thinks this important but practically he shows that it is not. The result is that he shortens his working life here, but lengthens it in the possible life elsewhere.

The average man of big affairs is one who has not paid much attention to the rules of health since he left college, if he happens to be a college man. He may have gone through four years of strenuous athletics there, but has done nothing of that nature since. His big powerful heart has gradually deteriorated into a smaller and rather flabby muscle,—a power engine of much less working capacity. His lungs, because of lack of normal exercise, have diminished in breathing capacity and power, but have increased in susceptibility to disease. His muscles are smaller and weaker because they have had comparatively little use. What would happen if he had to run half a mile at a fair pace to meet an emergency?

In the first place, he could not run that distance, but if he did attempt it, he would be exhausted and perhaps seriously injured or possibly killed. There is no physiological reason why a man of forty or forty-five should not be able safely and with positive benefit to run a half mile or a mile at moderate speed. How many men can walk upstairs at a brisk pace to their office on the eighth floor without being out of breath for the next quarter of an hour? He is very likely twenty or thirty pounds over weight, not of muscle or nerve or gland tissue.

but of fat, and fat is an almost lifeless tissue, of no value in such excess, but a burden to carry as a pack on the shoulders of a civilian going about his daily work would be. Further, it is an indication of senility or premature old age and is so considered by the life insurance companies. Again the organs of elimination have not been kept up to the highest point of efficiency and the waste accumulations and poisons are not properly got rid of; he is fatigued and tired when he should not be. He who sits down all day in a luxuriously equipped office is often more tired at night than the employee who has been working on his feet all day in the machine shop or packing room. His appetite is poor; plain, coarse, wholesome food does not appeal to him. He must be tempted by delicacies or awakened by alcoholic stimulants. Any slight excess in eating causes a "hold-up" in the digestive machinery. There is no margin of safety there.

He is more susceptible to disease because the body defences are unable to cope with invading disease germs. Because of nervous tension, resulting from great responsibility, he has to restore his nervous balance and comfort through the use of artificial stimulants. He starts the day's work on a caffeine stimulation, gets up an appetite for dinner through a cocktail; is soothed from the irritations of the day's work through nicotine; gets rid of the body waste products through the use of a cathartic; chases business cares away by amusement at the theatre, and is finally lulled to sleep until the next day through the kindly action of a sedative. Efficient living does not necessitate such a daily program.

According to statistics, the death rate in America is higher for the middle period of life, which is around fifty, than in any other great nation in the world and this is more particularly true of men who carry great responsibility. Unfortunately this is the period of greatest usefulness.

The diseases which are peculiar to men of this age in America are called the "diseases of degeneration," some of which are heart disease, hardening of the arteries, apoplexy, Bright's disease, or chronic inflammation of the kidneys, and diabetes. It is a matter of observation that an increasingly larger number of American men of prominence die as a result of one or more of these so-called "diseases of degeneration."

We do not as yet know the cause

of these diseases. There is no one cause; they are probably due to a combination of causes. Some which the indicator points to are: lack of sufficient vigorous physical exercise, over-eating, use of stimulants such as coffee, tea, tobacco and alcohol; excessive social obligations, and great professional and business responsibilities and irregularity of the functioning of the ductless glands.

It is astounding to think that the efficiency expert is so inefficient when applying his principles to himself. This is one of those strange human inconsistencies. Most men are content to live on a low level of mental and physical efficiency. If we are able to get out of bed, take our three regular meals and do our day's work, we say we are well, perfectly healthy. That is existence, not health. Our standard of health should include bounding vitality and endurance, a

spirit of optimism and invincibility resulting from efficiently working bodily organs. It should mean perfect digestion and elimination, capacity for restful sleep, an irresistible desire for muscular expression in the form of enjoyable athletic recreation or its equivalent, a contented and well poised mind, and a joy in just being alive.

If a man is mentally efficient enough to create systems of efficiency in his business he should be efficient enough to apply them to his own life and follow them.

Happily there is an increasingly larger number of men who are learning to live efficiently by taking time to play golf, attend gymnasium classes in the club or Y. M. C. A. work gardens, eat more rationally, and in general to obey the simple and obvious laws of health that any man with ordinary horse-sense could find time to obey.

## ASSOCIATION LETTER

BY WILLIAM ALFRED SAWYER, SECRETARY

THE Seventh Annual Meeting of the American Association of Industrial Physicians and Surgeons held in St. Louis, May 22 and 23, 1922, was more largely attended and far broader and more spirited in its discussions than any previous conference of the Association. The addresses offered and the more important discussions will be passed upon for publication as early as may be and the policies determined upon in executive session will soon begin to reflect themselves in new verve and broader activities. The official personnel of the Association remains unchanged.

The membership drive has met with success and has brought into the Association many men who are doing excellent work in the industrial field. The final results of the campaign will be described in the July issue of the *Journal*.

The generous response from the members regarding the writing of letters to prospective new members was most encouraging. The Secretary has received copies of a great many of these letters; the spirit shown in them gives assurance for the future up-building of the Association.

Bills went forward for the 1922-23 dues early in May and response has been rapid. It is hoped by the Secretary's office that none of the members will long delay in giving at-

tention to this important matter.

The following are new members: Dr. J. M. Barnett, Albany, Ga.; Dr. D. F. Armstrong, Auburn, N. Y.; Dr. G. F. Greeneleaf, Alton, Ill.; Dr. Richard Kemel, Cartagena, Columbia, S. A.; Dr. R. W. Burnett, D'Lo, Miss.; Dr. E. M. McCarty, Rumford, Maine; Dr. K. B. Steele, New York City; Dr. W. F. McNary, E. St. Louis, Ill.; Dr. O. C. Klug, E. St. Louis, Ill.; Dr. A. N. Dykes, Columbus, Ga.; Dr. R. W. Angevine, Rochester, N. Y.; Dr. F. G. Barr, National Cash Register Company, Dayton, O.; Dr. S. R. Light, The Upjohn Co., Kalamazoo, Michigan; Dr. S. R. Downing, Oakland, Cal.; Dr. C. C. Scott, Princeton, Ill.; Dr. P. J. Bowman, Ft. Bragg, Cal.; Dr. L. St. J. Hely, Richmond, Cal.

Information is in the hands of the secretary regarding a woman physician of excellent qualifications, a graduate of the Woman's Medical College of Philadelphia, 1920, who desires to enter industrial work; also regarding a trained industrial first-aid man, 39 years of age, with six years' experience, who has been connected with the first-aid department of a chemical plant, has considerable medical and pharmaceutical knowledge, who desires a new connection. The secretary's office desires to serve as a clearing house of information of this character.

# Report on Traumatic and Industrial Hernia\*

THE Report of the special committee of the Medical and Surgical Section of the American Railway Association on traumatic and industrial hernia is of great interest to all industrial surgeons. The subject, since the introduction of the Workmen's Compensation laws, has become a matter of great medical-legal importance.

The Committee divides the subject of traumatic hernia into three groups. The first group is made up of those cases in which there is direct injury by violence to the abdominal wall. These are the true traumatic hernias. Here the muscles are torn away by means of some sharp object and a hernia speedily results. None of the Committee had ever seen such a case but had heard of one resulting after an injury to the inguinal ring by the horn of a bull. The Committee, therefore, dismissed this group without further consideration. The third group is composed of those cases in which a hernia has developed in the presence of a weakness of the musculature but where no congenital pre-formed hernial sac existed. This type is also rare. The large group is the second which has been termed the industrial hernia or, according to the French, the hernia of effort, and it is this group which the Committee considers.

Hernia was formerly supposed to result when a trauma produced a sudden increase in intra-abdominal pressure which would force out the peritoneal sac and its contents. Since operation has become more and more common for the radical cure of hernia, it has been shown that hernia almost never is produced in this manner. It has been shown that a sac is pre-formed and that a hernia has developed gradually. It is true that the patient may have his attention first called to his hernia when a sudden increase in intra-abdominal pressure causes the entrance into the sac of a great amount of omentum or intestine. This fact has been advanced by Pellatin and Cloquet in the eighteenth century, but "Russell of Australia by his patient investigations forced us to con-

clude that practically all herniae are of congenital origin due to an open pouch of the peritoneum which has existed since birth." In support of this contention that hernia is almost always congenital, the Committee refers to the work of many authors. "MacCready, the greatest English authority on hernia, states that inguinal hernia is never due to an accident or single increase in intra-abdominal pressure."

"Graser, one of the highest German authorities, states that a hernia complete in all its parts can never arise at a moment of accident or by a single increase in the intra-abdominal tension be it ever so great." Moschovitz of New York not only claimed that true traumatic hernia is exceedingly rare but that when it did occur it occurred usually elsewhere than at the normal hernial openings. Mock, although he claims to have seen five cases of true traumatic hernia, states that this is a very rare condition.

## Traumatic Hernia Rare

The Committee reports a case in which a hernia developed following an injury and in which the patient honestly believed that the hernia was the direct result thereof. "A man of twenty-five years of age, an employee of the New York Central Railroad Company, with a history of never having had any swelling whatever in the region of the hernial canal, shortly after heavy lifting noticed a swelling in the right inguinal region. He came to the emergency hospital where the attending physician found a well marked inguinal hernia the size of a small egg in the right inguinal region extending well into the canal and upper scrotum. In the opinion of the surgeon this was one of the most definite cases in his experience pointing to a casual relationship between strain and hernia, and it might have been so regarded had not the patient consented to operation." At operation there was found "a pre-formed sac undoubtedly of congenital origin extending well into the upper scrotum two and one-half inches long and two inches broad, considerably thickened, firmly adherent to the overlying cremaster muscle. The nature of the sac clearly proved it to be of congenital origin, and in all probability the hernia had existed for months, or possibly years, although the patient may never have recognized it until the time of the un-

usual strain when a somewhat larger amount of omentum or bowel forced through the sac causing slight pain which first called his attention to the hernia."

It is a common occurrence in the New York Hospital for Ruptured and Crippled that a patient applies for an operation for hernia on one side entirely ignorant of the fact that he has almost as large or even as large a hernia on the other side.

In short, the Committee is convinced that "hernia is practically always due, (1), to the presence of a pre-formed sac or open pouch of peritoneum which in the inguinal variety follows the testis in its descent into the scrotum which point has failed to close in the normal way; and, (2), to the presence of structural weakness in the neighborhood of the hernial orifices due to poorly developed muscles or fasci. . . . The main point that cannot be emphasized too strongly is that hernia is never the result of a single strain or single intra-abdominal pressure due to any of the causes mentioned,—lifting, strain, etc., etc.†

"Although medical authorities agree as to the etiology of hernia, the decisions rendered before arbitration boards have not always been in accord. These boards have, as Sheen claims, "in the mass of ill-understood technicalities followed the lines of least resistance, have given judgment in favor of the working man—the *post hoc ergo propter hoc* view being naturally the existing one." Many of the State compensation boards are adopting definite policies along the lines of the latest medical teaching. Although there are no published records showing the results of the New York State compensation boards, the Board regards traumatic hernia as extremely rare."

However, there has been a trend of late in the other direction following a decision for the plaintiff in a case in which a hernia was supposed to have followed the strain of lifting. The State Industrial Commissions of Nevada and California have adopted rulings which coincide most nearly with the present day medical teaching.

The Committee closes its report with the following recommendations: (1) Render proper compensation for

†On the other hand it is a cumulative effect of a great number of strains spread over a considerable period of time.

\*Annals of Surgery, Vol. LXXV, No. 4, 467, April, 1922. Traumatic and Industrial Hernia. Report of the Special Committee of the Medical Section of the American Railway Association. William B. Coley, M.D., New York (Chairman), Chief Surgeon, New York Central R. R.; Southgate Leigh, M.D., Norfolk, Va., Chief Surgeon, Virginia Railway; John B. Walker, M.D., New York, Consulting Surgeon, Pennsylvania R. R.; C. W. Hopkins, M.D., Chicago, Chief Surgeon, Chicago & Northwestern R. R.; J. A. Hutchison, M.D., Montreal, Chief Surgeon, Grand Trunk Railway.

all cases of true traumatic hernia due to direct violence. Such cases are so few as to be practically negligible. (2) Make a physical examination of all applicants for position in industry no matter in what capacity. Such examination will determine the fact whether or not a hernia was present

at the time of examination. (3) Any case of hernia developing in the course of duty incident to the man's daily work should be treated as a disease due to special anatomical weakness on the part of the individual for which the company is in no way responsible. If it is considered wise

under certain circumstances to recognize any moral responsibility, let it be on the economic or humanitarian basis. The moral obligation should be understood to be strictly limited to such employees who have been found free from hernia at such time of previous physical examination.

## Recent Compensation Decisions

**W**HERE a defendant railroad company by contracts required its employees to pay fifty cents a month as hospital fees, agreeing to furnish them with medical and surgical treatment in case of injury or illness, and while there was no evidence of profit there was none to show that the fund was administered as a trust, or that the employees acquired an interest therein, the jury's finding that they were not charitable institutions and that the defendant was responsible for negligence was justified according to a decision by the District Court of Appeal of California. A rehearing was denied by the Supreme Court, February 20, 1922.—*Bowman v. Southern Pacific Co.*, 204 Pac. 403.

**T**HE Supreme Court of Georgia, February 14, 1922 upheld the constitutionality of the act regulating the occupation of barbers. The law does not violate either the equal protection or uniform operation provisions of the constitution. It has held that the state residents cannot attack the constitutionality of a statute on the ground that it discriminates against nonresident barbers.—*Cooper v. Rollins*, 110 S. E. 726.

**A** STATUTE which requires an employer to provide washrooms for employees after 30 per cent or more of the employees have decided by vote to ask and notify the employer to provide such washroom has been held unconstitutional as a delegation of legislative power in violation of the constitution. This decision was made by the Kentucky Court of Appeals, February 28, 1922.

The court states that the attempt is made to compel the owners and operators of certain businesses to build washhouses as a police regulation of the state. This is done not at the instance of the Legislature but at the instance of the employees. "The Legislature does not care at all about it, but leaves the matter entirely to the

employees of each mine or factory falling within a described class."—*Commonwealth v. Beaver Dam Coal Co.*, 237 S. W. 1087.

**T**HE Supreme Court of Illinois, February 22, 1922 held that the presence of pre-existing disease is not in itself sufficient to warrant a denial of compensation where such disease is shown not to have been of a character to disable the claimant. The facts are given in the opinion of the court:

The evidence in this record shows that Gulzter earned \$1,400 per year as loader, but, owing to the pre-existing disease, he could not load as many cars as a strong man. His earning power was depreciated by the disease, but was not destroyed. The award in this case was based upon that depreciated earning capacity. Plaintiff in error is therefore not required to pay compensation for the effects of the disease as it existed prior to the injury. The award in this case is sustained by the record.

**T**HE Supreme Court of Louisiana, January 2, 1922, decided that where an injured employee 59 years old refused to submit to an operation to remove the broken parts of his knee and which would require an anesthetic and resort to a hospital as a charity patient, his refusal was not unreasonable and did not defeat recovery for his disability under the Workmen's Compensation Act as amended.

The facts of the case are stated in the opinion of the Court. The plaintiff during his employment in the defendant's ice cream factory suffered an injury to his knee. The disability was not contested but it is said not to be attributable to the accident but to the refusal to allow an operation, "which would probably have cured him, and certainly relieved him of all pain and thus restored his ability to work." The patient hesitated about the operation. The surgeon's advice "that the operation would not be dangerous to life or health, and that the chances of success, in which event the use of the limb would be com-

pletely restored, and of non-success, in which event the limb would become ankylosed and rigid, were about even. Plaintiff would have had to be anesthetized; and being without means would have had to resort to the charity hospital as a charity patient which appeared to him in the light of a humiliation."

The Court said that in view of the age of the plaintiff and the seriousness of the operation which would require the administration of an anesthetic and the prejudice against the charity hospital, the refusal on the part of the plaintiff to undergo the operation was not unreasonable. "It was not the result of caprice, but of the natural dread of a surgical operation, always attended with more or less risk, especially after a certain age." Award upheld.

**W**HERE a valve on a steam boiler blew out and an employee ascended the ladder and closed the valve, descended and went to a window, then walked out of a door for a few steps, staggered and fell dead, the death was the result of a pre-existing disease of the heart and was not compensable as a traumatic "injury by accident" within the Workmen's Compensation Act defining compensable accidents, according to a decision of the Kentucky Court of Appeals, February 10, 1922.

Rusch was the employee of the Louisville Water Company which company was operated under the provisions of the Workmen's Compensation Act. The widow filed a claim for compensation and the Workmen's Compensation Board found that: "(1) The death of the decedent was not the result of traumatic injury by accident, but was due to pre-existing disease of the heart. (2) Over excitement and hurry at a critical moment taken in connection with a diseased heart caused the heart to fail." The decision of the Board was upheld.—*Rusch v. Lansville Water Co.*, 237 S. W. 389.

## A Platform for the Industrial Physician

**I**NDUSTRIAL medicine as a specialty has many proponents and many opponents. Industrial medical practice has many phases and exhibits many moot questions which have not yet been fairly formulated. There are, however, in the industrial medical group many virile thinkers who are organizing the field and are stating the case of industrial medicine in terms that are understood and acceptable both to industry and to the medical profession. Successive conferences mark orderly progression toward standardization and toward the correlation of industrial medicine with other specialties and with the field of public health. A very definite expression of this tendency is found in "A Platform for the Industrial Physician," under the signature of Otto P. Geier, M. D., director, Employees' Service, Cincinnati Milling Machine Company, Cincinnati, O., which appears in a recent issue of *The Survey*:

(1) We are living in an industrial country, in the era of "The Iron Man" with the resulting problems of health and physical efficiency.

(2) The industrial physician is the humanitarian answer of medicine to the health needs of all groups in this era.

(3) A physician devoting his whole time to the health problems of industry will deliver more units of useful surgery, of diagnosis, of curative care, of preventive medicine, of educational hygiene both collective and individual, than can possibly occur in the private individualistic practice.

(4) Placing the physician in industry, in stores, in banks, etc., makes health a part of the work-a-day life—adds it to the cost of doing business—puts health matters on a business basis.

(5) Consultation for diagnosis is encouraged by the industrial physician to a greater degree than by the practitioner because the industrial physician's failures stare him in the face daily; his uncured cases are advertised to all of the group, including management.

(6) The industrial physician sees the human machine under a load test. He sees it gradually get out of alignment and makes repairs before a complete breakdown occurs. Before and after an illness he adjusts the load to the ability of the weakened human machine.

(7) In the supervising of as few as 5 per cent of those gainfully employed the industrial physician perhaps makes more physical examinations per year where no illness is involved than are made on the other 95 per cent of the workers.

(8) Teaching the breadwinner the worthwhileness of personal hygiene, prompt attention to minor injury and illness, and the value of physical examinations means that more money will be cheerfully spent on these same facilities for the members of the family for whom he or she provides.

(9) In case of preventable illness or accidents under a system of industrial medicine the worker blames himself for the loss of wages and knows his employer is being robbed of production. In the other case, he usually curses his "bad luck" and feels that the physician in private practice is fattening on his God-sent misfortunes.

(10) Industrial medicine is one of the safe, sane stopgaps between whatever is unsatisfactory in the present system of medicine and that much heralded state medicine. It supplies the economical advantages of the organized treatment of large groups but preserves the real values of the individualistic competitive system of practice. Our statecraft is of such low grade that we should desist from overloading our Ship of State until the present political leaks are stopped.

(11) Industrial medicine, now supervising perhaps four million workers and employing the part or whole time of possibly two thousand physicians, has developed in spite of the indifference of our medical leaders toward this new specialty and has attracted many good men despite the patronizing attitude of the profession at large.

(12) The sanitarian should be the strongest proponent of the extension of industrial medicine, which is applying preventive medicine, collective and individual, in its most intense form—compelling periodic physical examination and demonstrating the value of the prompt seeking of medical attention and

early diagnosis. Sanitation and the detection of contagious diseases and of sources of occupational disease add further argument to the value of the industrial physician's work, to say nothing of his ability to furnish reliable morbidity statistics covering large groups.

(13) If mortality and morbidity are to be reduced to the minimum it must be through the more direct appeal to individuals to observe the laws of personal hygiene, to avoid quacks and nostrums, and to seek the physician's aid early. If such interest be placed on an economic basis, as in industry, this program will be definitely accelerated.

## Dr. Winslow to Safety Institute

**T**HE safety movement is not only humanitarian, but highly practical as well and the broadened scope of its activities in the promotion of human welfare is indicated by the addition to its personnel in the capacity of health supervisor of Dr. C.-E. A. Winslow, pre-eminently an educator, and one of the ablest scientists in the public health field.

tation and personal hygiene a third set of problems, involving the provision of medical and nursing care for the treatment of injuries and the early detection and preventive treatment of disease in its incipient and curable stages through systematic physical examination.

The Institute may properly aid in the solution of the problems outlined above by the following methods, to be worked out step by step as opportunity and resources permit.

(1) Our primary purpose is to develop in New York City a permanent national museum of safety, in which one section should be devoted to industrial hygiene and sanitation. This section will include exhibits dealing with lighting, ventilation, dust removal, factory seating and the like, with the elements of personal hygiene and with the organization of medical and nursing service. The visual instruction may be carried a step further by means of mobile exhibits and graphic illustrative material which can be carried from factory to factory.

(2) The teaching function of the museum should naturally be expanded through articles in *Safety* and through special bulletins and leaflets which would serve at the same time as reference material for members of the Institute and for the enlightenment of those who are unable to participate closely in its work.

(3) The message should be carried directly to the factories by the personal service of members of our staff. It is planned to give due recognition to sanitation and health in the system of organized lectures, consultations and inspections which is a part of the general program of the Institute. This service should be of inestimable value to the smaller industrial plants of New York City. A large plant can maintain its own staff for this purpose but the only salvation for the smaller factory is through some such form of co-operative service.

(4) Finally, it may well be possible in the future for the Institute to develop special training courses for industrial sanitarians, nurses and other specialists.

Dr. C.-E. A. Winslow becomes health supervisor of the Safety Institute of America.

Outlining the immediate plans of the Institute, Dr. Winslow states that activities will first of all be concerned with the general problem of factory sanitation. The health and efficiency of the employee depend, however, upon much more than environmental sanitation and so a second group of problems of almost as vital importance is that which concerns the personal hygiene of the worker, his posture and exercise, his nutrition, his working and resting hours and all the other aspects of the management of the living machine. Since the human body is not created as a perfect machine, we must add to environmental sani-

## School Architecture From a Health Viewpoint

New Type of Building Provides for Physical Well-Being of Children

BY W. B. ITTNER, ARCHITECT AND SCHOOL SPECIALIST, ST. LOUIS, MO.

A FEW years ago a co-worker interested in educational and social problems spent quite a little time at a remarkably well-equipped recreational center in one of our large cities. Here were indoor and outdoor gymnasiums, pools, showers, workshops of various kinds, and gardens. To him this kind of school, (for at first he mistook it for such) synonymous with free and controlled activity in a sanitary, wholesome, and inviting environment, was a revelation. He wondered why he had not heard of it before, why it seemed to be resting in apparent obscurity. He determined to visit the place as often as possible for a season. At every visit he was more and more impressed with the glory of it, with the beauty of childhood and youth under natural conditions. How spontaneous these boys and girls were! How alert, active, alive, and happy! Surely this school had an important message for the whole country.

But he, like the children, was not permitted to enjoy this child garden long. The first day of school came. The children vanished into a big brick prison-like building just across the street which he hadn't even noticed before. He went up to it, then inside. The darkness in the corridors blinded him. Could it be that the superabundance of joyous child life which he had witnessed and generously absorbed was now compressed behind closed doors? Yes, there they were in rows and seats, all poring over books or looking shyly up at a teacher who was talking to them. The air in the rooms staggered him; the unnatural

stillness palled on him. Were these the children he had played with across the street? Evidently so, for he recognized their faces and some of them dared to smile at him.

"When do you take the children across the street to their school?" he asked a little timidly of one of the teachers who was energetically erasing the blackboard in a manner that caused a chalk-dust cloud. "What do you mean?" she returned almost brusquely. "That is no school; it isn't even part of the public school system, and it would be better if it were somewhere else for nine months because it's awfully hard to keep the

children away from there. They just want to play all the time. It is no light job to get them to settle down to work after a summer of idleness over there."

Luckily this happened several years ago. Today it is an easy matter for any one to decide which of the two agencies referred to above was the real educational agency. All that the recreational center required to change it into the right sort of present day school was a set of class rooms. Practically all the other facilities were there.

Perhaps nothing indicates the rapid progress in educational evolution

Broad, well lighted corridors are a safeguard to children. Sanitary drinking fountains installed in most modern schools prevent the spread of communicable diseases.

A plant laboratory connecting directly with outdoor gardens is a feature of one of the better type of modern school buildings.

more emphatically than the insistent demands for a change of environment, the result of a change in fundamentals. Not so long ago gymnasiums and extensive playgrounds for elementary schools were considered extravagant, out of place. High school students, of course, had them long before the younger children. They were accustomed to a few luxuries while elementary school children were compelled to abide by necessities. Swimming pools and showers in any kind of school would have staggered taxpayers; and if any sort of propaganda had been developed among school children for combating enemies to health and community welfare, the school was criticized for wasting time and not attending strictly to business.

#### School as Health Agency

Now gymnasiums and showers are becoming as common as classrooms. Even our elementary schools are installing swimming pools; and any community building on a restricted site so that full playground accommodations cannot be secured is considered a back-number. Then there is the school auditorium, nature study, science laboratories and gardens. These facilities in the school afford excellent means for the accumulation and dissemination of health facts.

It is only necessary to enumerate a few of the actual health activities of the public schools to convince even the ultra-conservative that the school people, administrators, teachers, and parents are launching a vigorous offensive against the cause of physical

deterioration as well as carrying on aggressive measures to safeguard and promote the health of all children. (A.) Special studies are being made of the best lighting, heating, ventilation, sanitation, and safety of schools. (B.) Wholesome, sanitary, sunny and cheerful environments are being demanded for work, study, and play-quarters. (C.) School operating schedules are being devised so that pupils may move about occasionally. Constant sitting in a school seat in a crowded school room is deleterious to the health of growing boys and girls. (D.) The movable type of equipment which has freed children from the

rigid atmosphere of the old-time school room and encouraged free movement is another step toward better health. (E.) The attempt to make school life more like real living has resulted in a variety of activities, a variety of interests, consequently, a balanced life. (F.) The daily playground and gymnasium activities as part of curricular activities together with the various recreational attractions offered by the school almost continuously aid immeasurably in raising the health standard among girls and boys, and in forming habits for the wholesome and worthy use of out-of-school time. (G.) The periodic physical examinations, the special examinations, and the corrective measures developed to aid individuals to overcome physical deficiencies all tend to give to every child a full and natural development and indicate, beyond a doubt, that children today may go to school to get well. (H.) The preventive measures taken for checking the spread of contagion and exterminating the sources of health dangers are not only safeguards to the school, but to the entire community.

All of these activities and innumerable other related ones indicate at once that there has come a change in the fundamental considerations in education. Health has become an educational objective.

#### Why Education Has Changed

The more immediate causes for the change in fundamentals and vital considerations of our public education are easily detected. Social and industrial

Swimming pools are now installed even in elementary schools. They are recommended only when their proper installation and sanitary upkeep are assured.

changes have forced changes in educational thought and practice. Centralization of industry has caused fundamental changes in the living and working conditions of our great commonwealth. It has changed the home and created new community demands. Scientific experiments, educational surveys, and research have developed a more scientific attitude toward educational procedure. We know that children cannot learn unless they are in a proper condition to learn. We know now that physical, mental, and moral health is a fundamental in the learning process. A small number of progressive school communities in the country have been living agencies in exhibiting the limitations of the school of yesterday when applied to needs of today. By far the most pronounced cause in educational awakening has been the shock of the world war's revelations. The painful statistics regarding the physical defects of our drafted men constituted the most effective weapon in compelling the attention of the entire nation to preventive and remedial measures in early life.

#### Plants Plan for Health

Every school environment should be a model for health. Sanitation, good lighting, airiness and cheerfulness of surroundings are the eternal watchwords of every real school architect. The proper location of the school, an adequate site, and an efficient building plan ought to result in a physical environment that fairly radiates health and wholesomeness.

Movable class room equipment for the younger children gives opportunity for unlimited freedom of movement. The equipment in this room consists of small maple topped tables and oak chairs in two sizes.

No specific part of the school plant is more inviting, more stimulating to the youth of all ages, than large and well equipped outdoor play quarters. Perhaps no other factor in the school can do more to safeguard and promote physical and moral health. Certainly, playgrounds are the most natural enemies of delinquency and truancy, and no other part of the school plant attracts as powerfully during out of school hours.

Five acres is considered a minimum site for medium sized schools. This acreage will usually provide sufficient

space for the school building, the playground, gardens, and lawns. Of this space, two acres at least are required for physical education such as ballgames and the free and competitive exercises. High schools require more space than elementary schools, but large sites are desirable for all schools wherever possible.

Health activities within the building usually include gymnasium exercises, physical examinations, medical inspection, and instruction in personal and community hygiene. The scope of these activities varies all the way from the schools where practically all the work is developed by one physical director to the large complete schools where many specialists, such as physical examiners, nurses, gymnasium, swimming, and athletic instructors are employed, and the physical activities diversified so that the varying needs of differentiated groups may be met.

Two gymnasiums, one for girls and one for boys, showers, dressing-rooms, medical, and consultation rooms are essential to a comprehensive physical education program. In large schools, corrective gymnasiums may be necessary, and swimming pools, if properly installed and carefully supervised, always constitute distinct assets. Experience has proved that 50' x 80' is a normal floorspace for gymnasiums. In the matter of location, the unvarying requirement is that gymnasiums must receive maximum light and ventilation. This is scarcely possible if the location is be-

Covered roof gymnasiums, equipped with toilets and drinking fountains, constitute an aid to all varieties of open air activities with children. The floor of this one is covered with battleship linoleum.

low grade or if low-ceilinged basement rooms are used. Gymnasium floors should be above grade. Windows on three sides are desirable. Maximum ventilation and light are thus assured. Ordinarily, gymnasiums should be brought to the playground level and lead directly to the playgrounds. Separate shower, locker, and dressing rooms for boys and girls are, of course, necessary. The number to be installed and the arrangement depends almost wholly on the number of students to be accommodated at a time.

Clinics, medical, and instructors' rooms need to be closely correlated and should open directly to the gymnasiums. They may lead directly or indirectly to the playground. Maximum sunlight and air are as essential to these rooms as to gymnasiums and pools.

Roof gymnasiums are made readily available by roofing the area over the regular gymnasiums. When properly arranged and equipped with drinking fountains and toilets, they become valuable for all types of physical welfare work and for open-air class work.

Aside from the general school environment, and the physical education group, the workshops and laboratories may also be considered health promotion facilities. The activities in the various workshops develop and train more particularly the eye, the arms, the hand, and many of the smaller muscles. It is granted, of course, that the motor activities in the workshops also have another distinct purpose, but the fact that they serve for health assures them a prominent place in the health curriculum. Such activities, for instance, as woodwork, clay modeling, forge, foundry, sheet metal work, nature study, horticulture, gardening and animal husbandry are examples of some of the motor activities that minister definitely to health, aside from their own intrinsic value.

Drinking fountains and toilets in schools may become a deadly menace to health. Maximum light and ventilation must accompany the proper installation and distribution of toilets. A special ventilating fan operated independently of the general ventilating system is frequently in-

stalled and is always recommended.

The medium-sized auditorium of 600 to 900 capacity is recommended for schools since it functions most effectively for practical use. A central location upon the first or main floor is usually the most satisfactory both from an educational and administrative viewpoint. Unlimited natural lighting and ventilation are secured by this location.

The indoor and outdoor physical education activities together with the supplementary health work of shops, laboratories, and class rooms may be unified and crystalized in the school auditorium. The movies, health demonstrations, and special visits from the city health corps and others constitute an impetus to the actual physical education work in the school which is scarcely possible in other ways. The auditorium furnishing space for student congregation, is the natural center in the school for the various discussions on personal and community hygiene, for the organization of health-promoting student-bodies, and for distribution of all health literature.

## The Child and the Convalescent Home

BY A. LEVINSON, CHICAGO, ILL.

IF HUMAN life were so regulated that each one could live in comfort, the need for convalescent homes would not exist. The healthy child would stay at home and the sick child would stay a short while at the hospital and then return home. Under present conditions, however, convalescent homes are a necessity, and the best one can do is to learn of the indications for sending children to those homes and the means of so regulating these institutions that they will do most good and will not become a source of hardship on the physicians and parents.

It should be the endeavor of every physician to keep the child in the hospital for as short a time as possible. It is well known, however, that a drop in temperature does not mean the recovery of the patient. As often pointed out, convalescence may last one day and it may last a lifetime. Acute conditions are usually marked by a slow convalescence. The atmosphere in the hospital, however, is not very compatible with convalescence. Besides, keeping convalescent children in the hospital would congest the hospital and crowd out

acute cases that have great need of the hospital. It is, therefore, important to send the child to a convalescent home for two or three weeks in cases where the illness has been acute, where recovery is expected in a short while, and where home conditions are unfavorable. Subacute and chronic conditions do not belong in the convalescent home although unfortunately in many convalescent homes the chronic cases outnumber the convalescents. One type of subacute disease, however, belongs in the convalescent home and that is subacute endocarditis. If there is anything to be done for heart sufferers, it is very early in the disease, after the first or second attack and before decompensation takes place. Aside from all drugs, rest is very essential. The rest, however, must be complete and prolonged. Convalescent homes may be of great service in such cases. Children who have passed through an attack of acute endocarditis leave the hospital under the impression that they are entirely well. On their return home they very often forget the ailment and become very active. It is, therefore, necessary to look for some

means of restraint, and since it is hardly possible for a hospital to keep such cases more than a few weeks at a time, it is proper to send these cases to convalescent homes where they can be watched and regulated according to instructions from physicians. However, once a case of endocarditis becomes chronic, and goes through more than two or three attacks or decompensation, a convalescent home is not the ideal place for it. If the child cannot be taken care of at its own home, it should be placed in a special home for cardiacs or in a home for chronic invalids.

The question often arises as to what to do with cases of chorea. These cases, as a rule, do not do well at their own home because they cannot be controlled by their parents. They do fairly well at the hospital where they get complete rest. The question, however, remains whether they are acute enough for a hospital. It seems that chorea may just as well be treated in a convalescent home as in a hospital. This method of treatment would relieve the congestion in many children's hospitals and at the same time would lessen the

expense of treatment and would afford the patient just as good, if not better, chances for recovery.

Each patient entering a convalescent home should have a complete diagnosis, a thorough examination, and specific rules for treatment, either medical or non-medical. Sending a child to a convalescent home to rest without thorough knowledge on the part of the caretaker, whether she be nurse or lay person, as to the diagnosis and method of treatment or supervision is an additional expense and a burden on the community. Unless the convalescent home is in close contact and works in cooperation with a hospital, it does not fulfill its function and does more harm than good.

Each convalescent home should be under the direct supervision of a physician. The ideal way should be to have a resident physician at the home. Next to that, daily rounds made by a physician will answer the purpose. It is unfortunate that many convalescent homes in this country are being "supervised" by men of reputation who simply add this position to the list of many and varied other posts of honor. A convalescent home needs a fair proportion of the time of an energetic physician. It is preferable to have a trained nurse in charge of a convalescent home. Occasionally, however, a lay person will do just as well. Whoever takes care of the home must, however, have a thorough knowledge of children and must have the interests of children at heart.

Contagion is one of the problems that confront every convalescent home. Wherever children come together contagion develops unless strict means are taken to prevent it. It, therefore, behooves everyone concerned to use all means available to prevent contagion. Separate utensils for each child, boiled linen, sufficient air, frequent examination, and isolation of all ill patients will go a long way to prevent contagion.

Every convalescent home for children should have a teacher of occupational therapy so that the children can pass their time contentedly. The occupation should, however, be prescribed for each child individually. The same applies to exercise. Every convalescent child needs some exercise but this must be suited to the child's needs and physical ability, otherwise a dilatation of the heart or a rupture of an unhealed wound may result.

Food constitutes a problem of paramount importance in every convalescent home. Not every child will eat everything given him, nor may

every child have everything it desires. It is, therefore, necessary to have each child's diet prescribed by the physician in attendance. Some times a child will not eat certain foods given him at the convalescent home because he is not used to eating these at his own home. I know of children who refuse vegetables at hospitals or convalescent homes because they seldom get them in their own homes. In such cases the nurse in attendance will perform great service by insisting that children at the convalescent home eat the proper food, thereby training the children for the future.

The practice of sending a child to a convalescent home where there are also adults is not very commendable. Older people like to recount their many ailments and troubles. Children, especially convalescent children, should not be subjected to such morbid influences. On the contrary, every effort should be made to see that the child forgets all about his sickness. Therefore, the ideal place for the convalescent child is the convalescent home that caters especially to children.

Just as it is important not to keep children too long a time in a hospital, it is very important to limit the stay of children at a convalescent home. As soon as a child has recovered sufficiently so that there is no danger of an immediate recurrence of the disease or a dilatation of heart, he should be sent home. It might be wise to instruct the mother while the child is at the convalescent home in methods of feeding, of resting, of medication, of general discipline.

In order to be of full service to the community, the convalescent home should be more than a rest cottage. It should be a center of instruction for mothers and other relatives on the best methods of how to take care of a child who has recently been ill, and above all, how to keep the child well.

### Food Value of White Flour

The Food Reform League in a communication to the London *Lancet* seeks to direct more attention to the mineral content of oatmeal and whole wheat meal and to the dangers arising from the milling of cereals. The energy requirements of the body vary from 2,750 to 5,500 calories per day according to the work of the individual. They are mainly satisfied by fat and carbohydrate in the proportion of 90 g. of fat to 550 g. of carbohydrate. Carbohydrate is chiefly consumed in the form of starch from white wheat flour in bread, cakes, and

pastry. The average quantity eaten per day may be reckoned as two pounds of bread, which furnish two thousand of the necessary calories. Proteins, salts, and vitamins are the other essential constituents of the diet. The protein and salt requirements are easily satisfied by the ordinary mixed food, but such food may not supply the vitamin requirement. Like proteins, definite amounts of each vitamin are required daily to keep the body in perfect health, and yet the amounts have not been determined.

The germ and outer portions of the cereal grains supply B-vitamin, the absence of which from the food leads to beri-beri, as has been clearly demonstrated both in the case of polished rice and white wheat flour. Seeds of grains and legumes are the natural foods richest in B-vitamin. The milling processes remove the B-factor from the grain, and its loss is not easily made good in the diet of the poorer classes. Flesh and fish are poor in respect to this vitamin, eggs are good, and so are most fruits and vegetables; yeast contains this vitamin in considerable amount.

The addition of yeast to flour in the making of bread does not compensate for the vitamin lost in milling. No attempt is made to compensate for it in making cakes, etc., for which baking powder is used. Milk is variable in its vitamin content, and can hardly be considered as rich in B-factor. The loss of B-factor in the grains will only be replaced if eggs and large quantities of vegetables and fruits are eaten.

As B-vitamin is a highly important constituent of the food, and is only amply supplied by the germ and outer parts of cereal grains, health is not promoted by the preference of the population for white flour. Whiteness does not represent goodness. The people should be encouraged to eat whole-meal flour, so that they can get a proper supply of B-vitamin. Highly milled flour is also deprived of good protein, A-vitamin, and salts. It is of special importance that patent cereal foods for infants should be prepared from the whole grain.

In a State-wide effort to inform the general public more fully how to preserve mental health and prevent mental disease, the Mental Hygiene Committee of the New York State Charities Aid Association has secured the voluntary services of thirty-one noted psychiatrists and other authorities on mental hygiene for public addresses. The Association which has carried on a State-wide campaign for the prevention and earlier treatment of mental disorders for some years through this Committee, celebrated its fiftieth anniversary on May 11th. Stanley P. Davis is Executive Secretary of the Committee.

# David A. Mountain Home for Aged Physicians

## A Project for the Care of Those Grown Old in the Service of Their Fellowmen

By JOHN A. LAPP, L.L.D., CHICAGO.

THIS country has been slow to realize the importance of providing sufficiently for those who, having given their lives for the welfare and advancement of mankind, are in their later years incapacitated and unable to perform the duties of their vocation, perhaps even to provide for their own needs. War pensions have been granted to soldiers

up the standards of professional life. Many break down in what should be the prime of life while many others reach old age without adequate means of support. The people think well of their doctors but they realize all too little the economic burdens which keep generous hearted men from accumulating resources against the time when through accident, disease, or old

about to be softened by the establishment of a great memorial home where physicians who are aged, incapacitated, or infirm may pass their final years in comfort, surrounded by all of the means of contentment and physical care that their grateful friends may provide and in the companionship of others of their own professional interests and of libraries and laboratories where they may keep up their interests in their life's vocation.

Proposed model for the David A. Mountain Memorial Home. Plans for the erection of buildings contemplate an expenditure of \$250,000 as a beginning.

and sailors; civil pensions are given to superannuated Federal employees; teachers, policemen, and firemen are pensioned in several states and cities as are also civil employees in some cities. Ministers of certain denominations are provided for in old age and a few industries provide pensions for aged employees.

The bulk of people, however, face old age without the certainty of means whereby they must sustain life properly after their powers fail. Even those who have some property are harassed when incapacitated through age by the thought that it may not last them to the end of life if the end should be postponed for long.

To no body of people does old age bring greater need than to the physicians who have served long and faithfully, giving of their time and money to aid the poor and near poor, weakening their physical powers by excessive work and exposure, and compelled to bear heavy expenses to keep

age they are no longer able to serve.

It is a happy announcement to the physicians of the country and their friends that the indifference of the world toward the aged physician is

### Located in Western New York

In the valley of the Genessee river in western New York where the romance of Indian life left an imperishable impress stands the little village of Caneadea near the site of a former Indian village from which it received its name. Among the pioneers of this valley was David Mountain who developed out of the forests a splendid farm on the slopes of the hill two miles from the village. Here he raised a large family and inspired them all with the zeal for higher education. The whole resources of the newly developed land were spent in their education. For fifteen years this farm supported from one to three of the family in college. Six members graduated from higher institutions of learning. Two of them became physicians and surgeons of distinction, and these two have now taken to heart the

Golf links and tennis courts will offer recreation.

The David A. Mountain farm in western New York, which has been presented by the two physician sons, Drs. William H. and Stephen V. Mountain, as a home for aged and infirm physicians, the same to be a memorial to their father, David A. Mountain.

problem of their fellow practitioners and have opened the way to a hopeful future for those who are aged and infirm. The old home farm of two hundred acres which has been developed by modern methods and equipment to a high state of cultivation has been presented by the two physician sons, Dr. William H. and Stephen V. Mountain of Olean, New York, founders of the Mountain Clinic, as a home for aged and infirm physicians, the same to be a memorial to their father and to be known as the David A. Mountain Memorial.

The gift has been made to an organization called the Physician's Home, Inc., of which Dr. Robert T. Morris is president; Dr. Ralph Waldo, vice president; Dr. Silas F. Hallock, 36 East 65th Street, New York City, secretary; and Dr. Albert G. Weed, 152 West 57th Street, New York City, treasurer. In addition the Board of Directors includes Drs. Warren Coleman, Max Einhorn, Wolff Freudenthal, Francis Huber, and Stephen V. Mountain.

It is the intention of the Board of Directors to occupy the farm house at once and to build a modern home as soon as possible. Plans for the erection of buildings contemplate an expenditure of \$250,000 as a beginning. Under the present tentative plans, there will be two large dormitories in one of which will be installed laboratories for experimental purposes. Golf links, tennis courts, and croquet grounds are being laid out and there will be a complete gymnasium including swimming tanks, bowling alleys, and billiard rooms. Provision has been made by the Board of Supervisors of Allegany county in which the in-

stitution is located for the construction of a paved road from the village to the farm. Many additional features will develop as the plan grows.

In addition to the dormitories and sanitarium, the Board of Directors may find it advantageous to build

David A. Mountain and family. This picture was taken in 1888.

small cottages where physicians and their wives may live by themselves and yet have the advantages of the

facilities of the institution.

It will doubtless happen, too, that many physicians who have small amounts of money may desire to purchase with it the privilege of care for the rest of their lives, thus making their small savings permanently provide for their care throughout old age. The home will offer also a resting place for doctors whose health may have become broken in their work. It will combine, therefore, not only the features of an institutional home but also of a sanitarium.

Meeting, as it undoubtedly will, a great social need, this institution may be expected to grow to large proportions. Many developments, unthought of at present, will take place bringing nearer and nearer the ideal of social security to those who have done so much to make others secure.

### Eyesight of School Children

The results of testing 22,000 children as to the prevalence of defective eyesight are published in the annual report of Dr. H. P. Newsholme on the public elementary schools in the North Riding of Yorkshire. Percentages are given by *The Lancet* as follows:

Of the boys 8 per cent and of the girls 8.5 per cent were shown to have grossly defective vision.

The chief points brought out were (1) an increase of the proportions of serious defects as the children advance in school; (2) the prevalence is greater among girls; (3) visual defects increase in prevalence with increasing urbanization.

Genesee River, where the trout are plentiful.

# Exterminating Flies a Public Health Duty

BY W. DWIGHT PIERCE, PH.D., MANAGING DIRECTOR, BIOLOGICAL DEPARTMENT, MINERAL, METAL AND BY-PRODUCTS COMPANY, SAN MATEO, CAL.

THERE is no task more important assigned to those who govern a city than that of preserving the health of the community, but it must be remembered that no public servant can carry out his duties without the full and hearty support of those who put him in office. Public health in municipalities is a very difficult thing to maintain because it depends upon the personal actions of every individual sojourning in the city or even passing through it. When persons realize to the utmost that their personal actions at each minute in the day have their bearing upon the health of those about them, and that one bit of carelessness on their part may, through no desire and even without their knowledge, become the starting point of an epidemic that will snuff out many lives, they will begin to rearrange their actions.

Citizens cannot expect to have health inspectors forever dogging their steps to see that their actions are sanitary, nor can they expect that they will be able to look into their backyards every so often, for the public treasury will not bear the expense of complete sanitary policing of a big city. It is incumbent upon them as individuals, therefore, to do their part right, to keep their yards free from trash and filth, to keep their homes sanitary and well ventilated, to protect the public when they are ill from being infected by their actions, and in no wise to commit nuisances which would imperil the lives of others. These are their duties as individuals.

If they are vendors of food to the public, it is their sacred duty to preserve that food as long as it is in their care, free from all contamination. They can do no less and do their duty. No honest store keeper will wait for the food inspector to visit his place and force him to obey the laws. As a matter of fact, there are many things which the store keeper should do to protect his food that there are no laws to force him to do except the law of society which impels us to do unto others as we would have them do unto us.

It cannot be said that at the present moment the food vendors of our cities are doing their whole duty in preserving food from contamination while it is in their care. Possibly this

is because they do not know the facts concerning contamination. Personal observations in many stores seem to indicate a complete indifference to one of the biggest causes of food contamination in the cities of America, the common fly.

One would think that all that has been written about the fly would have resulted in some attention being paid by store keepers to this pest, but apparently the subject has not yet been put to them in such a way that it has struck home. The subject is one that does not permit of delicate handling, and not until the full enormity of the fly's crime sinks into the public conscience will full results be obtained.

There is no fouler visitor to the home than the *Musca domestica*. They are denizens of the filthiest disease centers of the city and should not be permitted to visit decent homes, nor should stores where these filthy customers are allowed to enter and sample those same foods be patronized. No fly ever touches food without leaving some form of filth on that food.

## House Fly Breeds in Filth

The house fly lays its eggs in filth, that is in garbage, manure, and excreta. The fly itself feeds on all these things and sputum as well. All filth contains the germs of decay or disease. The fly maggots hatch from the eggs in the midst of germs and they constantly pass multitudes of germs through their bodies. The passage of germs through these living bodies intensifies their virility and increases their longevity, although some of them are digested by the body fluid of the larvae. Many of the germs taken into the body of the maggot remain there and thrive in this perfect medium until the maggot has passed through its development into a perfect fly. This fly may carry for days and weeks the germs it took up as a larva in its body. A fly may wander as far as fifteen miles in a few days. When a fly feeds, it often moistens its food with liquid regurgitated from its crop. This liquid vomit contains germs. It also drops a speck of excrement which is alive with germs. If a speck of excrement or vomit happens to fall on moist food, it finds a good culture medium for the germs. For this reason milk is a dangerous typhoid carrier. The flies

bring the infection from filth to the dairy and the milk man carries it throughout the town to his customers. The specks may even be placed on supposedly clean dishes which a little later are used as food containers and thus contaminate the food placed in them.

Every time this germ-carrying fly lays eggs, it deposits in a film around these eggs some of the germs. The eggs may be laid in supposedly harmless substances free from disease organisms, but the harmlessness is no longer, for the germs thus deposited will be passed through the bodies of all the maggots breeding in this substance and when they become flies they in their turn will distribute them to new foci until finally contact is established with human food and a so-called sporadic case of disease breaks out with no apparent connections with any known case.

All this means only that the house fly is the principal agent for carrying disease germs from filth to the food of man. The fly must be suppressed at its source.

To this end an adequate and regular removal of garbage and manure and a thorough system of sewage with no exceptions are necessary. If sewage pipe systems are inadvisable or impossible, then there must be installed a septic tank system, by groups of dwellings, or for each separate house. Rural communities are more dangerous to a town sometimes than the conditions within the town. In other words the sanitation of every house in a county should be under the strict supervision of the county health officer. We live in a day when it is recognized that the misbehavior of a single individual may imperil the lives of a community.

The commissioner of health of Greenville County has been authorized to establish a traveling dental clinic to operate for three months for the benefit of the school children in the rural districts of the country. This is the first clinic of its type in South Carolina. A number of county fair associations in Illinois have applied to the State Department of Public Health for assistance in conducting Better Baby Conferences in connection with fairs to be held next fall.

# High School Cafeterias Fill Dietary Need

By LAURA C. FAWCETT, DIRECTOR OF THE HIGH SCHOOL LUNCH DEPARTMENT, EAST ORANGE PUBLIC SCHOOLS, EAST ORANGE, N. J.

**T**HERE is sweeping over the United States today a gratifying interest in the health and nutrition of children. We have been, as a nation, too slow in realizing the importance of this phase of our national health. One way in which this interest has been manifested is the effort which progressive school systems are making to bring health education into the public schools. This health education, though still somewhat vague in its aims and methods, has brought to light one important fact, namely that many school children frequently from comfortable, middle-class homes are undernourished.

The cold lunch brought from home or purchased from the corner bakery has been partly responsible for this condition for when good school lunch rooms have been installed, a marked improvement has been shown in the health of the boys and girls.

Over the entire country, school cafeterias under trained dietitians have made splendid beginnings. Where the leadership has been wise and support has been given by boards of education, these school lunch rooms have been a success financially and otherwise.

The cafeteria method of serving school children has been found to be the most efficient, because by this method large groups of children may be served in a short time and in a comparatively limited space. This method is also the least expensive method of feeding, and since school lunch rooms should be self-supporting, this is an important point to be considered.

In the East Orange High School lunch room, an average of one thousand one hundred girls and boys are served daily. The accompanying menu gives some idea of the cost and variety of foods served. For instance, the Wednesday menu includes the following:

Vegetable soup .....	\$.05
Meat loaf and mashed potatoes...	.15
Creamed chicken on toast.....	.15
Scalloped potatoes .....	.05
Lima beans (dried).....	.05
Ham sandwiches .....	.05
Baked beans .....	.05
Nut and cheese sandwiches .....	.05
Lettuce sandwiches .....	.05
Waldorf salad .....	.10

Ham and potato salad .....	.10
Chocolate pudding .....	.05
Fruit cup .....	.05
Ice cream .....	.10
Cocoa .....	.05
Milk .....	.05
Home salted peanuts.....	.07
2 rolls and butter .....	.05

On a separate menu board, food combinations at various prices are posted each day as suggestions to those who have no definite selection in mind. For instance, say on Wednesday, the following combination menus will be suggested: For 15c, vegetable soup, 2 rolls and butter, chocolate pudding; for 20c ham and potato salad, milk, fruit cup; for 25c creamed chicken on toast, lettuce sandwich, cocoa. Other combinations suggested to the children are baked beans, lettuce sandwich, Spanish cream for 15c; fish balls, cold slaw, rolls and butter, Brown Betty for 20c; and meat balls and mashed potatoes, pineapple and cheese salad for 25c.

Milk chocolate was removed from the menu as it was found that the children were eating too much of it.

The lunch room is under the supervision of the home economics department, and every effort is made to maintain high standards of food and service.

A study of lunch room menus forms a part of the year's work in all food

and cookery classes. Elementary science and chemistry classes also touch on the subject. Frequently, articles published in the high school paper bring to the pupils and the home interesting phases of food and nutrition as observed in the lunch room. These articles are written by pupils of the school in a column headed "The Lunch Room Observer." It has been possible through this column to put across in an interesting and informal manner important facts relating to food and health.

The lunch room is as important a part of the school plant as the gymnasium or auditorium and deserves the same thought and consideration in planning a new building. After the original equipment has been installed, the lunch department should be entirely self-sustaining. All salaries, wages, repairs and replacements, installation of new equipment, gas and electricity should be paid from food receipts. A well equipped, wisely managed school lunch room will always be a success financially. From a health standpoint, it will be an asset to both school and community.

The University of the State of New York, Albany, has issued its second revised edition of bibliography bulletin 69 listing books on health as related to the school child.

A corner of the East Orange High School lunch room during the busy hour. Different menus each day and suggested combinations at low cost offer to the pupils a well balanced noon-day meal.

# The Summer Camp, a Builder of Health

## Physical Training for All Should Be Aim of a Well Regulated Camp

BY EDWIN DE MERRITTE, DIRECTOR, CAMP ALGONQUIN, ASHLAND, N. H.

**L**IFE in a properly recognized summer camp is now recognized as a potent factor in the up-building of strong, vigorous, progressive boys and girls. The value of such a camp cannot be over-estimated. Much depends upon the make-up of the camp. If it be beneficial, it must take account of location and sanitation, moral surroundings, food, properly controlled exercise, division of time, numbers, and supervision.

The small camp has a great advantage in supervision and personal touch. The outdoors has a life giving quality; it invites close study and furnishes a never ending source of joy as nature unfolds itself to the willing observer. The pure air of the woods, bird, animal and plant life, the structure of the earth, and the study of the heavenly bodies offer strong inducements to wide-awake boys and girls to make this study part of their recreation in the open. With these there is no over-exertion, no physical exhaustion, no mental weariness. They furnish a physical and mental stimulus. The tendency to commercialize the camp is a serious drawback to the welfare and health of the child which must be the first consideration. The whole future of the child, mental, moral, and physical may be either strengthened by wise supervision or ruined by careless leadership. A wise supervision produces and gives the opportunity to develop initiative and self-reliance. The camp director has a responsibility which he cannot safely delegate to others. He alone is responsible to the parents for the care of the child.

The camp life, the associations, the teaching by example, and the moral influence of the council have a strong bearing on the future of the child at an age when the mind is receptive and the tendency to imitate is strong. As most children are hero worshippers, the need of care is therefore great. If we look after the health and normal surroundings of the child, we have laid the corner stone for a life of usefulness. Unless the camp makes this its duty, it fails in its work.

Athletics form a large part of the work in most camps. In fact too

many camps are little better than training schools for preparatory school athletics. The athletic trainer is chosen for his fame as an inter-scholastic or intercollegiate athlete, and consequently as a drawing card rather than for his sterling character and ability to lead and guide in the right way. His sole object is to turn out a winning team regardless of results. He does not consider that the growing boy must be trained gradually, must never be allowed over exertion, as the overtaxing of his strength is often fatal to the promising athlete for all future time. In training a winning team only a few get the necessary care. The rest are neglected.

### Athletics for All Members

To illustrate, a few years ago a high school in Massachusetts had a winning foot-ball team. This team was sent west to compete with a winning team there. Of the five hundred boys in this school only about fifty did any regular athletic work in the open air. The reason given by the boys was "What is the use? We do not stand any chance to get on a team." Here 90 per cent of the boys,

the ones who really needed careful systematic, health giving training in the open were sacrificed that the school might have a winning team. For the above reasons the system of inter-camp athletics is wrong, as the camp which is not giving to every member of the camp the same thoughtful care is not doing its duty, and a camp cannot serve two masters successfully. Within each camp boys of like age and strength should be opposed to each other in contests adapted to their strength, and the results of games lost and won should have the same rank as those of the older boys.

It is to those children who are indolent by nature and who have never known the thrill of legitimate competition that special attention must be given to round out the body and give to them that physical strength so necessary to stand the mental strain of an active business life in later years. To do this a slow and systematic beginning must be made to mould gradually the hitherto untrained muscles into one symmetrical whole, with every muscle trained to perform its duty, the lung power strong and the heart able to send the

The Director of the camp, who eighteen years ago, to save himself from becoming prematurely old, worked out the system of exercising which the camp follows.

Agencies in 244 other cities

*A flexible shoe for your flexible foot*

Nature, in her wisdom, designed your foot arch to flex when you walk. Why restrain it in shoes that are rigid and without natural lines? "The foot is like a cantilever spring," wrote a noted doctor. "The Cantilever is the most comfortable shoe I have ever worn," said a trained nurse; and another woman said, "In Cantilever Shoes I feel as though I were flying."

It is because of the *flexible shank* and *natural lines* of the Cantilever Shoe that you will derive such comfort from it. And because of its graceful appearance and its harmony with this Spring's shoe styles you will see it worn wherever daytime costumes are worn. Fine workmanship, splendid materials and reasonable prices add to make the Cantilever desirable.

The graceful carriage and youthful walk of the Cantilever Woman are often admired. Her feet are free. She walks naturally, with a minimum of effort. Flexing with

every step, Cantilever Shoes make her feel as though she wore the wings of Mercury.

Though you may not be conscious of it, there are few things that spoil a good disposition quicker than shoes that nag you. Nerve strain, leading to backache, headache, and even to pains like those of rheumatism, may be caused by high heels and by shoes that bind and restrict the feet. Many writers on health and beauty subjects are now pointing out the importance of a woman's shoes in respect to her health, happiness, and personal attractiveness.

You were given two marvelously constructed feet. At the nearest Cantilever Store, try on a pair of shoes suited to their needs. Keep your feet well and spare yourself the misery that has come to so many women. If wrongly designed shoes have already begun to injure your feet, a change to Cantilevers will help them. Weakened arches will be strengthened by proper exercise; your improved circulation will make you feel better and look better.

If none of the listed dealers is near you, write the manufacturers, Morse & Burt Co., 1 Carlton Avenue, Brooklyn, N. Y., for a nearby dealer's address and for the Cantilever Booklet, which tells some things you will be glad to know about your feet.

**Cantilever Shoe**

Endorsed by Women's Colleges, Women's Clubs, Public Health Authorities, Physicians, Osteopaths, Directors of Physical Education, Editors, Stage Celebrities and prominent women everywhere.

Some of the members of the camp who have built up strong, muscular bodies as the result of consistent training. The second man from the right came to the camp as a boy suffering from heart disease and through graduated exercise became normal.

blood regularly to every part of the body with ease.

Some years ago the writer had a boy placed in his care in camp with definite instructions from the family physician not to allow him to engage in any active competition on account of heart trouble. Baseball was forbidden on the ground that the running of a base might prove fatal. Before the summer was over his heart trouble had nearly disappeared and he was able to enter into the regular life of the camp without any harm. After one year's practice of the physical exercises learned at the camp, giving to them about ten minutes per day, he was as strong physically as other boys who were normal at the start, and had followed the same course in physical training. He is now a successful engineer and ably doing his work. This is one case where careful, sane building of the body in one camp season changed a boy from a weakling to one able to meet the demands of a useful and successful career. Last year a boy about thirteen had an operation for appendicitis early in June and came into camp a week late in consequence. By the middle of August he was taking the regular camp activities and swam his fifty yards in thirty-five seconds with ease. These facts are mentioned to show what can be done by careful supervision and training.

The system at this camp for developing body and health is simple and not exhausting. It was worked out by the director eighteen years ago to save himself from becoming prematurely old. Now at seventy-six he is doing twelve to fourteen hours work a day and can follow the hunt from daylight to dark with younger men and not be the laggard. He takes his exercises daily. What one

has accomplished in the way of health, others can.

The camp physician, usually an untrained medical student, is not necessary if a competent local physician is available for an emergency. The teaching of First Aid is within reach of every camp, and each member should be required to learn bandaging, stopping the flow of blood, and what to do in any emergency. The teaching of First Aid may be so attractive that each child in the camp feels it his or her duty to learn it accurately.

#### Swimming Hour Supervised

Under this head comes also life saving which every camper should know. The swimming hour may be made invigorating and health giving or a source of danger. This is especially true of camps on inland, fresh water lakes. All swimming periods in fresh water should be made short, not over twenty minutes at most. If this plan is carried out, the camp will be benefited and every member of the camp given a new lease of health. Where boys are allowed to stay in the water as long as they please they lose vitality, become enervated, return home unfitted for their school work. This is a frequent complaint of parents and injures the value of camp life in the minds of many people. During the short swimming period as much progress can be made under proper supervision as in a longer time and the camper is always fit.

Another drawback to a successful summer in health building is the camp store. The writer has before him a list of camps which buy confections from one manufacturer. The inducement to purchase for the camp store is the big margin of profit possible. Of the one hundred twenty-

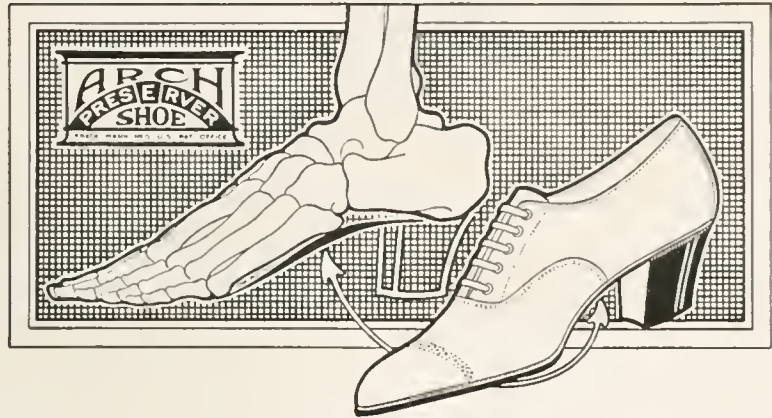

nine camps on the list, how many are profiteering, and how many find their young friends benefitted by the over dose of confections? Children will go the limit. They lack discretion as to the amount they may eat at one time with safety. But the larger the sales the larger the profit.

The food question in camp is of vital importance. The kitchen and dining room should be in charge of experts and run on purely sanitary lines. Where the campers are expected to do a large part of this work, the conditions cannot be otherwise than insanitary as this is not the work for which they go to camp, and the work is done in a hurry to have time for things which are a legitimate part of their camp life. Plain, simple, nourishing food with variety enough to avoid too frequent repetition should be available in every camp, and only the best grades should be supplied. In the end the best grades will be found the cheapest as there is practically no waste as is invariably the case with cheaper grades.

In writing this article, the writer has endeavored to point out a few of the prevailing evils which an experience of thirty-six years as camp director has brought to his notice. During this period he has had a camp physician for only four seasons, but the health of the camp has been so good that there has been nothing for him to do. This should be the condition in every camp. It is always possible to keep the whole camp in such a healthy condition that each and every member is always ready to take part in all that pertains to camp activities.

The camp has come to stay. It provides for the growing boy or girl the right associates, the right leaders, regular hours, good food, sanitary environment, and plenty of exercise in the open. More and more camp directors are studying all these questions and are improving their conditions each year. Contrast with this the ordinary life of the child who either stays at home or is taken to some summer resort where the life and environment are not conducive to good manners, good morals, or good health. Few parents give to their children that watchful care which they receive in a well regulated camp, under wise supervision at all times. In camp, under wise leaders, the prevention of things which are injurious to health is much easier than in a hotel or at home. Above all, parents should investigate a camp before sending their children there.

# What reason is there for fighting Nature?

**T**HE easy way, the sure way, to maintain health is to work WITH Nature!

And wherever Civilization has opposed Nature there has been trouble. Especially in shoes is this true.

Nature requires a firm walking base underneath the entire foot. Nothing difficult to understand about that, because the function of the foot is primarily to bear the weight of the body.

Yet, Civilization, for some unknown reason, evolved our ordinary shoes which leave the foot arch (the most delicate part of the foot) without support of any kind. This causes a strain; the foot weakens; there is discomfort; health is impaired.

In the past this form of footwear was excused on the ground that people desired heels. Today there is no excuse, because women can wear heels; can have the styles they wish; and yet wear shoes that give full length support to the foot. The Arch Preserver Shoe works WITH Nature. It offers all that the so-called stylish shoes give—plus foot health and comfort.

A concealed, built-in-arch bridge makes the Arch Preserver Shoe support the foot as normally and comfortably, as when going bare-footed.

Write for special booklet 55 "Why the Arch Preserver Shoe preserves the feet." Ask us the name of your dealer, if you don't know him, or call the "Tel-U-Where" Bureau.

The Selby Shoe Company, Portsmouth, O.

## THE ARCH PRESERVER SHOE

## Training of Hospital Executives

A REPORT of more than ordinary significance has just been issued on the subject of training hospital executives. The report represents a study covering nearly two years under the auspices of a committee created in the winter of 1920 for the purpose consisting of the following members: Dr. David L. Edsall, Dean, Harvard Medical School, Boston, chairman; Dr. W. L. Babcock, Superintendent, Grace Hospital, Detroit; John G. Bowman, Chancellor, University of Pittsburgh, Pittsburgh; Miss Elizabeth Flaws, Superintendent, Wellesley Hospital, Toronto; Dr. S. S. Goldwater, Director, Mt. Sinai Hospital, New York; Miss Annie W. Goodrich, Teachers College, Columbia University, New York; Prof. Paul H. Hanus, Department of Education, Harvard University, Cambridge; Rev. Charles B. Mouliner, S. J., President, Catholic Hospital Association of the United States and Canada, Milwaukee; Dr. Frederic A. Washburn, Director, Massachusetts General Hospital, Boston; Dr. Willard C. Rappleye, Chicago, executive secretary.

The information gathered by this committee has been condensed into a compact report of twenty-eight pages. It may be called a fundamental report leaving details for the most part for elaboration by others. It is essentially an attempt to place the hospital in its setting in community affairs. The position of the hospital is set forth as follows:

The common ground upon which the patient, the community and the professional groups meet and represent the general type of organization which, with proper amplification and development, can best meet the problems suggested, is the hospital. It evidently occupies a strategic mid-position and has open to it a great opportunity and a corresponding obligation, not as an institution for the salvage of human wreckage but as a coordinator of activities—professional, economic, and social—in their application upon the problems of health. In such a conception, the hospital represents not the administration alone but a cooperative organization of workers and leaders devoted to the ideals of their respective professions.

After setting forth the functions of the hospital a concise definition is given:

The hospital may then be defined as a community organization which provides facilities and personnel for rendering the highest possible grade of health services to patients, professional groups, and the community; for

educating the community to demand and support adequate health services and sound health policies, for educating additional personnel and professional groups in technical fields and in cooperative endeavor; and for advancing our knowledge of disease and its prevention through technical research and appropriate organization.

The organization necessary to carry out these functions is described thus by the Committee:

The plan of organization to execute these complex functions must be developed to secure the highest efficiency of performance at a minimum of effort and cost. The chief function of administration is to create an environment conducive to the spontaneous, creative expressions of the groups working within the organization and to relieve the professional workers as much as possible of non-professional and non-technical duties; to provide, then, the facilities and machinery by which the fullest expression of functions may most easily be obtained. A sound plan of organization must be constructed in relation to the fundamental unit of operation, to the objectives sought and to the personnel it serves, not the reverse.

The unit of operation of the hospital about which the whole organization should be built, upon which all activities must ultimately converge and constituting the reason for the existence of the hospital and professional groups working with it, is the patient. Only through him and contacts arising therefrom can the hospital find its fullest expression of service. A patient in the last analysis is only a human being either with or threatened with incapacity, physical or mental. He represents the cross section of a human life and as much is the resultant of many forces in the past—hereditary, industrial, environmental, economic, social—which may have conspired to predispose or contribute to his present condition. It is frequently quite as necessary, then, to understand and to interpret these human and social factors as it is to appraise technical and biological factors in order to secure a correct diagnosis, to guide treatment intelligently and to propose methods of prevention. The administration of a hospital under this conception must necessarily be based on the community as the unit of operation, not the institution.

"The hospital executive, as executive officer of the governing board," it is declared, "stands between the policy determining body and the hospital work and closely in contact with the professional groups. Such an officer should be able to interpret community needs, the methods to be devised to meet them, the objectives sought, the fundamentals of sound organization and administration, and be able to mobilize and direct the self-expression

of diversified activities toward a common goal."

After pointing out the inadequacy of existing means of training leaders in the field of hospital administration the report outlines a course of study which it is definitely stated should be given "under university auspices." It lays down a general course of training under ten heads giving weights to each as indicated: (1) Public health, 20 per cent; (2) social sciences, 15 per cent; (3) organization, 15 per cent; (4) hospital functions and history, 10 per cent; (5) business science, 10 per cent; (6) institutional management, 10 per cent; (7) personnel administration, 5 per cent; (8) community hospital needs, 5 per cent; (9) physical plant, 5 per cent; (10) jurisprudence, 5 per cent.

A significant point about this course of study is the large proportion given to public health and social sciences, emphasizing as these facts do the enlarged place of the hospital in community life.

The report considers the preliminary requirements for training, the subject matter for basic training, educational opportunities for present hospital superintendents, and research in health problems. It does not attempt to indicate where training centers should be located except that they should be under university auspices, the selection of training centers not being within the function of the committee.

The report concludes with the following compact summary:

The growth of a sense of community responsibility in matters of health is leading to a demand for coordination of the diversified activities and professional groups concerned with these problems. The hospital represents in general the common ground of most of these activities and groups and a type of organization which may readily be adapted to the functions of coordination, education, and service. It occupies a strategic position in the whole field of community health and provisions for the adequate training of hospital executives would constitute a fundamental contribution to the entire program.

The Ohio State Board of Vocational Education is asking the Ohio State Medical Association to help in securing a census of disabled men and women in Ohio who may be eligible for vocational training to overcome any economic handicap resultant from injury or disease.

and Weak  
Arches  
Can Be  
Corrected

To restore the physiological functioning of the muscular structures it is essential that the depressed Longitudinal Arch be progressively raised and supported in position to remove all excessive muscular and ligamentous strain. This is successfully accomplished by the use of

### *Dr. Scholl's Corrective Foot Appliances*

and a series of foot exercises for the purpose of strengthening and restoring usefulness to the foot and leg muscles.

Doctor, there are thousands of cases of painful feet with symptoms of arthritis and gout that are caused by weak arch or flat-foot. Statistics show that growing children are as susceptible as adult men or women regardless of their position in life.

Be prepared for your next case—make a physical examination and prescribe a treatment as orig-

inated and perfected by Dr. Wm. M. Scholl, and as used by over twenty thousand successful practitioners.

#### Valuable Pamphlet Free

If you will write your name and address on a post-card we will send you, post free, a new pamphlet just published—"Foot Weakness and Correction for the Physician," and include a chart of foot exercises.

## Chicago's Health Pageant

**P**RACTICALLY every phase of disease prevention is capable of dramatic presentation if only the dry as dust figures we encounter everywhere are visualized and have the breath of life put into them. This the Health Pageant undertakes to do. Models of sanitary lay-outs for camps or rural homes are in stern contrast, side by side. The peregrinations of the fly show him to be an unworthy visitor, one to be excluded by fair means or foul. If babies in the proportion of one in seven suffer from preventable disease, the shocking fact is brought home by the decimation of the rank and file infants as they appear in a moving picture. The committee, realizing that the public, although interested enough in the concrete fact or the specific instance, is unconscionably hard to move by generalizations and has realized the necessity of animated figures and demonstrable facts in driving home the health facts pertinent to the local situation.

The Health Pageant carries a distinct message in matters of nutrition. The pure food show will show exactly what constitutes a balanced ration, its cost, and how it may be prepared. It undertakes to show not only that health is a purchaseable commodity, but that there is a distinct relationship between dietary habits and longevity, that tuberculosis is amenable to control, and that community health is largely a matter of community initiative. It shows the busy housewife how to arrange her budgets satisfactorily from a health standpoint, and the average man how to be a good citizen from the angle of welfare.

The old conception of health activities having to do largely with police powers, protecting the public

against contacts, and in certain instances forcing upon a reluctant public the necessary health practices is giving way before health measures understood and self-imposed. Hence the intensive effort that is being made to direct aright the educational features of the Exposition by health departments, Federal, state, and municipal.

### Making Palestine Sanitary and Healthful

The political aspects of the situation at Palestine have rather overshadowed in the public interest the aspect of the indefatigable effort of the scientific medical workers in Palestine to make the country fit to live in from a sanitary and medical point of view.

The Medical Unit, ably directed at Jerusalem by Dr. J. M. Rubinow with the assistance of Miss Henrietta Szold, formerly of New York, and Miss Sophia Berger, has established four hospitals in Palestine and a sanitary service that reaches throughout a large part of the country, the North and Galilee. It has established a nurse, a physician, or a druggist in every Jewish settlement in Galilee, and a corps of sanitary inspectors as watchful and active outposts in the campaign against malaria. These inspectors, young bacteriologists under their chief, Dr. Kligler of the Rockefeller Institute, work through the country, watching the purification of the water, looking after the prophylactic administering of quinine, the construction of sanitary waste systems and the removal of garbage, the extermination of the fly nuisance and the prevention of disease in general.

A special corps of physicians and nurses is carrying on careful school

inspection work for ten thousand children, with the purpose of extending this service to not only the Jewish communities but the children of other communities as well. The recent gift of an x-ray equipment by an American visitor will greatly facilitate this part of the work.

Infant mortality is great in Palestine largely because of the poor and unsanitary home conditions under which, in many instances, babies are ushered into life. To cope with this difficulty an obstetrical ward has been established in the hospital at Jerusalem.

There is urgent need, of social service nurses all over the country. At present the Medical Unit keeps up an infant welfare station with a milk distribution centre attached to it.

The work in Palestine and the problems it involves, being purely humanitarian and philanthropic, as distinct from any political aims or activities, is expected to have the support not only of the various sects and races in Palestine, but of well-wishers in the work of human betterment and the alleviation of human ills everywhere.

That poor vision is a contributory cause of delinquency is the opinion of Judge Charles L. Brown of the Philadelphia Municipal Court. Every sixth child passing through the medical department of the court shows eye conditions which cause social maladjustment.

A receiving and clearing bureau for the Protestant child-caring institutions of New York is about to be established. Plans for a model group of buildings for the purpose have been filed with the State Board of Charities by Mr. Edwin Gould, who will erect the buildings and support the undertaking. The new bureau is the outcome of many months of study by specialists.

Last year one million people attended the Health Pageant in Chicago, held on the Municipal Pier. Ingenious devices made vivid the story of health and the penalties the people pay for indifference or ignorance. The Second International Pageant of Progress will be held July 29 to August 14, 1922.

## New discussion of the value of yeast treatment in suppurative skin diseases

**I**N a chapter entitled "Boils, Furunculosis, Carbuncles, Acne" fresh light is thrown on the question of yeast therapy in relation to these and other suppurative skin diseases.

Up-to-date sources and authorities are quoted so that the physician, if he wishes, can follow up the condensed material of this chapter by further reading and research.

The author says in the opening paragraph of the chapter:

"The use of yeast internally, while usually effective alone, should always be considered supplementary to any necessary local treatment. And boils that have reached the suppurative stage at the beginning of treatment should of course be opened with the necessary surgical precautions and after treatment. It will usually be found that boils just starting will abort, and one of the great advantages of the

use of yeast is the prevention of recurrence. The rapidity with which a group of boils in various stages of advancement will often dry up and disappear is astonishing. When surgical intervention is necessary, the use of yeast will shorten the period of discharge and hasten the healing process.

"It is better to start at once with three cakes a day taken before meals. Yeast may be administered plain or with salt, on crackers, toast, in milk, water or fruit juices.

"It is important that the bowels should be kept freely open. This is accomplished by the yeast, but if this action becomes excessive the dose should be diminished. For the prevention of recurrence and in order to raise the resistance of the body to a normal level the yeast should be continued for several weeks after a cure has been effected."

The book from which the foregoing paragraphs are taken, gives in compact form the result of modern study of yeast. It is published by The Fleischmann Company and is distributed free to physiological chemists, doctors and hospitals. Write for a copy, addressing THE FLEISCHMANN COMPANY, Dept. Y-6, 701 Washington St., New York

## Science Aids the Deaf

**C**URIOS interest has run wild in its effort to understand the phenomenally high degree of the development of the senses of touch and smell exhibited by Willeta Huggins, aged seventeen, blind and deaf, but able to detect colors through her sense of smell, read newspaper headlines, talk over the telephone, enjoy music, carry on rapid conversation through her sense of touch, and to do a score of other things not usually considered possible to persons so handicapped.

The spectacular means of communication developed by those in whom certain senses are abnormal or lacking offer sufficient proof of the possibility of establishing through special training such means of communication as are essential to the mental development of these handicapped children. In order that a child with impaired hearing may eventually attain the highest possible degree of efficiency, his training must differ somewhat from that of the child with normal hearing, and this modification in training should begin with the onset of deafness.

The chief cause for failure in training the deaf is that the condition is not detected early, or parents postpone opportunity for special training beyond the auspicious moment for good results. If in the first year of life, when naturally the child first begins to react to sound, special meth-

ods were substituted and scientifically and consistently carried out, the disastrous results of deafness as a handicap could be greatly reduced. The tragedy of the matter is that "not one mother in ten thousand knows how to meet the situation as it should be met, unless some special guidance is provided."

The educational treatment of deaf

Wide World Photos.

Willeta Huggins, of Janesville, Wis., stone blind and entirely deaf, has developed an acuity of the sense of smell which enables her to detect colors and to become aware of the presence in her vicinity of anyone she knows. Psychologists have been unable to discover by what means she interprets these things.

children, as in other defects, presupposes careful diagnostic study. It needs to be established whether total deafness exists for all kinds of sounds or whether certain noises or sounds are heard. These "rests" of hearing are now utilized to the utmost in the educational methods utilized for their training. Every teacher is aware of the favorable effects of even vowel hearing on the speech of deaf children. Even though this vowel hearing is only an indefinite blur of sound, it may be sufficient to enable the deaf child mechanically to produce some or other of the stronger vowel elements, and with marked benefit on the quality of voice and speech. Constant repetition of these realized sounds give them a definite character. The sequence of practised forms becomes associated with lip reading and greatly aids recognition and association.

Writing in the *Lancet* on the educational treatment of residual hearing in deaf children, A. J. Story, chairman of the National College of Teachers of the Deaf, argues the necessity of enlisting in the service of the individual child whatever advantage, however small, he may possess of the natural faculty. The best means of conservation is one that utilizes the existing hearing power to carry on further the oral and general education.

In many cases parents and medical men do not understand the present conditions of schools for the deaf. Many associate such schools with an atmosphere of perpetual silence, whereas in actual truth the modern school for the deaf is often vocally noisier than the school for hearing children in the effort to develop in them added powers of vocalization and of association through phonetic memory. The proper training of these children calls for their classification according to the history and degree of deafness, and their mental condition. It is supposed that all that medical skill can do to prevent or improve the deafness has been done before it is accepted as a settled condition and educational methods devised.

Especially is it important for parents and those responsible for the children to understand that along lines of specially adapted training lies their only hope. The message of Dr. James Kerr Love, the well known aurist of Glasgow, in a note to parents may safely be followed in the handling of deaf children.

"If your child has been born deaf, or if illness has caused deafness and loss of speech, his hearing will never return. The exceptions to this statement are so few that they are not worth considering in thinking of the future of your child."

### Red Cross Leader Summoned

Henry P. Davison, who died at his Locust Valley, L. I., home on May 6, was a masterly organizer in the business world, but the chief monument to his memory will be the unselfish service he gave to his country in mobilizing the forces of the American Red Cross to meet the emergent conditions of the war. The Red Cross movement throughout the world, and the American Red Cross in particular, have suffered a serious loss.

Wide World Photos.

This new Helen Keller learned to talk with people by placing her hand upon the larynx. She then found she could carry on a conversation by placing her finger tips on the head or the chest of the speaker. She can follow a lecture or an orchestra merely by holding a sheet of paper in the air.

## Veterans' Camp at Saranac

THE Veterans' Mountain Camp, promoted and largely financed by the New York Department of the American Legion, promises at last the greatly needed home for convalescent soldiers.

The Barbour camp in the Saranac region of the Adirondacks, the replacement value of which is estimated at three hundred thousand dollars, is to be acquired for \$85,000, together with 1,200 acres having a shore line of 2.6 miles on Big Tupper Lake. There is the usual equipment of farmhouse, root cellar, barn, etc., besides a handsome recreation hall and four large motor boats. The luxurious main camp is to be used as an infirmary for some twenty bed patients. Log lean-tos are to be built for convalescents, permission having been granted to place them on the lakes and streams of the adjacent forest pre-

serve, with kitchens and mess rooms conveniently located. The average stay of patients in city hospitals is about two weeks, but the Legion hopes to extend the time to three weeks. With one hundred beds in the open the mountain camp will be able to care for 1,700 patients a year. The only condition for admission will be an honorable discharge from service and genuine need of treatment. Preference will be given to veterans of New York State, but when possible all comers will be welcomed.

It will cost twenty thousand dollars to equip the camp and it is estimated that the annual running expenses will be fifty thousand dollars. To cover present expenses and provide for gradual enlargement, the Legion has undertaken to raise an endowment fund of \$2,500,000 to place the project on a permanent basis.

## Different Dietary Systems

A SOUND knowledge of dietetics is more valuable than the practical exhibition of drugs, states Thomas Dutton, author of "Digestion and Diet," writing in the March issue of the *Medical Times*. He goes on to affirm that through his dietetic psychological system he is able to show highly satisfactory results in various forms of digestion, rheumatism, gout, obesity, and nervous diseases. The more practical the knowledge of the treatment with drugs, combined with a scientifically selected dietary, the more successful the physician. Dutton does not think, however, that the faith should be pinned to any definite diet for one and every complaint. Discussing the relative values of different diets, he proceeds:

Taking an impartial and unbiased view of food values, I believe the manual worker and the man or woman who take a great amount of physical exercise daily, can obtain the best and most economical food value from a mixed diet of meat, fish, vegetables, cereals and fruit. The professional man and the sedentary worker can spend a more healthy life on the pseudo-vegetarian diet with milk, cheese and eggs, with fish added on those days when any violent physical exercises is undertaken, but to place a navy on raw vegetables and nuts, seems to me absurd and, according to our knowledge of food factors, would simply tend towards the creation of a degenerate race and bring on many diseases of the internal organs and the nervous system.

That the most economical manner

of getting protein is from the flesh of animals, birds and fish is undoubtedly true, but there is a great drawback against this source of food, namely, that we have to kill in order to obtain it. I, therefore, would willingly join a league to try the experiment of abstaining from all animal food for a period to ascertain the result of doing away with this protein, in order to avoid the necessary "killing." Perhaps it would be advisable for the professional community and sedentary workers to test this dietetic scheme before asking the manual worker to join. Of course, it will be useless unless about 75 per cent of the population fell in with this humanitarian dietary.

The great drawback to the pseudo-vegetarian, vegetarian, or raw vegetarian and nut dietaries is the expense, trouble, and the skillful cooking required to make such food digestible and appetizing. At the present time either of these would cost twice as much as the average mixed dietary.

Only one housekeeper in a quarter of a century really understood the cooking of vegetables properly, much less the making of substantial vegetables, with cereal dishes as a meal of resistance.

Besides the cooking, a vegetable diet requires a good, sound, healthy digestion, particularly if the food is not cooked well. As an example, I have had two patients lately with severe forms of indigestion who have been under the care of a so-called specialist who prescribed raw vegetables and nuts. The patients could neither digest one or the other, but, when placed under a diet consisting of minced poultry and rabbit, white fish, with properly steamed Brus-

sel sprouts, spinach and celery, made rapid recoveries.

The up-to-date, scientific, practical dietarian does not adhere to any system of dietary, but when consulted about disease takes every phase of the patient's condition, occupation and environment into consideration, and then frames a diet-card from previous practical experience and physiological studies of food values.

## The Sleep of Elementary School Children

In the course of his school medical inspections Malcolm Gross has made a consistent effort to determine (1) the amount of sleep obtained by elementary school children, and (2) the relation existing between the amount of sleep and their condition of health. Records for winter and summer were made on the lethargic appearance of the child, in behavior or otherwise, on whether the child has to be waked in the morning, and on the length of time the child sleeps. The tabulated results of these records constitute the material reported in the *Lancet* on the basis of which he decided it to be advisable in dealing with children up to the ninth year to add one-half hour all round to the time of going to sleep as given by the parents, and of one hour for children from twelve to fourteen years.

A large number of children are shown to have insufficient amount of sleep. His conclusions are that (1) elementary children do not get enough sleep in winter; (2) they get still less sleep in summer; (3) for the diminution in summer the Summer Time Act is partially responsible; (4) the Summer Time Act need have no effect where parental control is what it should be; (5) the ideal procedure is to improve parental control and knowledge and continue with summer. Until this improved control and knowledge is obtained summer time is detrimental to the vast majority of children. Parents should be encouraged to obtain longer sleep for their children the whole year round.

While the material in hand does not justify conclusions as to definite relationship between this lack of sleep and the presence of certain defects, such relationship is indicated and calls for further observation.

Emphasis is made of the fact that the habits of sleep in children in the groups aged twelve to fourteen are far less under the control of parents than they should be and it is difficult to get them indoors and to bed as early as they should. The percentage of children showing fatigue signs increases with the age of the children.

# The Hygiene of Pregnancy

BY OUR OWN LONDON CORRESPONDENT

IT IS now generally recognized that the hygiene of pregnancy is a very important factor in the well being of the race and an essential branch of preventive medicine. The woman who has enjoyed a healthy heritage and environment need not fear pregnancy. On the contrary, during this period she finds better health and enhanced vitality. Unfortunately, in these days of stress and strain, and especially in a country as is England, in which the majority of people are in overcrowded cities and towns and live and work under unhygienic conditions, the woman as a rule has neither enjoyed a healthy heritage nor environment. To go through the time of pregnancy is a strain on the reserve powers of the system. If these powers are there, all well and good; but if they are lacking the small store of reserve powers that exist are chained and vitality is diminished and each succeeding pregnancy further depletes vitality. The functionally sound pregnant woman is vitalized by her condition, while her functionally unsound sister suffers desperately during this period.

But it is not only the woman who suffers—it is also the unborn child. And this is what renders antenatal care one of the most important branches of preventive medicine. Heredity and early environment play large parts in the question. With regard to heredity, little can be done immediately or in the near future to improve the situation. The only hopeful sign of the times is that work is being done for infancy today in this and other countries which will favorably influence child bearing in the times to come. But environment can be dealt with and bettered almost at once. Included in the question of environment are some of the most insistent social questions of the day.

The British Royal Commission on Housing which sat in 1885 pointed out three evils of bad housing which have a most direct bearing on the health of the mother and her unborn child. It was concluded by this commission that: (1) Poor housing diminished personal cleanliness and physique. (2) The sickness rates were high in such dwellings. (3) The death rates were higher than in most favored localities.

It might have been said what is beginning to be realized now, that rickets, that bane of city children, is al-

most as much a disease of environment as of unsuitable and defective diet. Women born in such environment and whose childhood is spent under such conditions cannot be expected to bear healthy children and the deterioration of the race is progressive.

The water supply in some British cities and towns is deficient and inadequate, although on the whole the water supply in British urban districts is good. The nutrition of British women who live and work in cities and towns is bad. The working people of the country domiciled in industrial centers exist on a less nutritious and worse cooked diet than probably any people living under similar condition in any part of the globe. Lady Barrett, a most distinguished lady consultant and dean of the Woman's Medical School London, writing on the subject in the *Journal of State Medicine*, March last, says that she is anxious to urge three measures which, in her opinion, are among the most important for the relieving of the prolonged hours of work and faulty nutrition of the working mothers of many countries. These are communal kitchens and dining rooms, commercial laundries fitted with all modern mechanical appliances, and day nurseries available for the chil-

dren of home-making mothers on washing days or during hours of recreation. Central heating and electric light in working class homes would also add greatly to the health and comfort of the whole family.

The maternity centers here have done much good and Dr. Eric Pritchard and others who have initiated and developed the system deserve well of the community, but the maternity centers have scarcely touched the problem of the small home, with its cooking for husband and children, the washing and drying in a small space, the costly storage of small quantities of coal and the problem of food storage or larder. All these, in the opinion of Lady Barrett, would be eliminated by the communal kitchen and the communal well fitted laundry.

With respect to the care of the woman during pregnancy, Lady Barrett highly applauds the establishment of ante-natal clinics which is going on so rapidly. At these clinics women can be examined early in pregnancy, and those whose health is at all doubtful can be kept under constant medical supervision. It is very desirable that the small ante-natal clinics near the homes of the women should form part of a maternity center which should provide educational classes, dinners or milk for expectant or nursing mothers where required, and dental treatment, so that the evil factors of carious or septic teeth may be eliminated during pregnancy and lactation.

## Census of the Blind

GR<sup>EAT</sup> interest is being shown all over the world in the figures of the United States Bureau of the Census of the Blind for 1920—52,617 blind persons, as against 57,272 in 1910, says Winifred Hathaway, Secretary of the National Committee for the Prevention of Blindness, in a recent issue of the *New York Times*. The National Committee for the Prevention of Blindness is naturally keenly appreciative of the comment on the report which suggests that a decrease in preventable blindness is indicated as a result of improvement in medical knowledge and of the education of the public. The Committee is confident from its experience and investigations that blindness from preventable causes, especially blindness from babies' sore eyes, has decreased perceptibly in proportion to the increase in population

during the last decade. Indeed, if this were not so the Committee would be deeply conscious that its energies and the funds placed at its command had been misdirected.

It cannot, however, accept the figures of the census as even approximating the actual number of the blind. It has always contended that the census figures of 1910 were altogether too conservative.

In the United States census of 1920, New York state is reported as having a blind population of 4,205 persons. The New York State Commission for the Blind has nearly completed a registration of all blind persons in the state. To date 10,982 have been registered, with one county still to be heard from. The Commission does not consider this figure final, since verification of every name on the list by the field agent has not

# Science demands economy in food consumption

**I**N CONSIDERING the scientific requirements for an adequate supply of good, healthful, wholesome food, the economic aspect of the problem cannot be ignored. If economy of production will insure a greater supply, then economy of production should be practiced in the interest of science.

For instance, granted that the public welfare demands an adequate supply of wholesome dairy products, the use of skimmed milk for cooking is an economic advantage because it adds just that much to the essential food supply. In this case it is also a scientific advantage in that it increases the use of dairy products in the diet.

Experience has shown that skimmed milk alone is not a satisfactory cooking liquid because it lacks the shortening and enriching value of fat. In HEBE this deficiency has been supplied by the addition of highly refined, easily digested vegetable oil.

HEBE is pure skimmed milk evaporated to double strength enriched with vegetable fat. It is produced in modern, thoroughly sanitary condenseries, sealed hermetically and sterilized in the container. HEBE is frankly labeled as to its contents and uses and is just as frankly advertised and sold.

*"Today's Food Problem"* a booklet published especially for physicians, health officials, dietitians, public health and industrial nurses, tells the story of HEBE and its relation to the food supply. It, with another booklet, "HEBE, Its Dietetic and Economic Value," will be sent free, together with a can of HEBE for examination and trial. Address 2622 Consumers Bldg., Chicago.

**THE HEBE COMPANY**  
Chicago                      New York                      Seattle

yet been made. The Commission has, however, verified the lists for the counties of New York, Bronx, Kings, Queens and Richmond, (comprising Greater New York) and finds a total of 5,556 blind persons. Thus in New York City alone there are 1,351 more blind than shown by the United States census for the entire state. Judging from the verifications already made, and allowing for all possible discrepancies, such as duplication of names, erroneous listing of one-eyed persons as blind, etc., the Commission is confident that the final lists will total well over nine thousand blind persons in the state—that is, more than double the United States census figures. Should the same proportion hold in other states, the list of the blind will more nearly approximate 105,000 than 62,617.

In considering these figures, several items must be taken into account: (1), that the figures of the 1910 census were evidently quite as conservative as those of 1920; hence though the actual number of blind in the United States at the present time does not reach the lamentable total of 105,000, this doubtless represents not only an actual decrease in number, but an even greater decrease in proportion to the increase in popula-

tion; (2) that there was a great increase in the number of industrial workers employed in hazardous occupations in the decade, especially during the war; (3), that the war blind constitute a group the cause of whose blindness is, we trust confined to the decade.

The united efforts of national, state, and local safety organizations of the National Committee for the Prevention of Blindness, together with the improved conditions under which accident compensation is administered, are tending to reduce eye accidents in the industries, heretofore one of the chief sources of preventable blindness. Many public health agencies are directing their energies to the elimination of social diseases, another of the leading causes of preventable blindness and deterioration of sight. Efforts being made along other lines are too numerous to outline here. Recognition of the fact that blindness from preventable causes has decreased during the last decade despite the unusual consequences, direct or indirect, of a great war should encourage not only continued effort, but should give impetus to an even greater output of energy to eliminate every possible cause of needless deprivation of the power to see.

solubility, various dried milks differ in their capacity for reconstitution. (8) The curd produced by rennet in reconstituted milk is flocculent and finely divided, in contrast to the firm, tough, and cohesive clot produced in raw milk.

The report of the British investigation of dried milk for infant feeding is quoted as saying that dried milk is, perhaps, "when all considerations are taken into account, the most generally useful of all the available preparations of cows' milk, this when dried milk is made carefully under hygienic conditions from a good quality of cows' milk." The observation was made that results of feeding to sickly infants, even when the condition was grave, have been admirable. The report goes on to say:

The physical and chemical changes produced by the processes used in the preparation of dried milk so alter its character that it is better borne by the infant's stomach than ordinary cows' milk, whether raw, boiled, or sterilized. The dried milk is easily and completely assimilated. It is palatable.

The drying of milk for general use would do away with all of the emergencies necessary in the handling of liquid milk. Saving the cost of refrigeration, special cars, breakable containers, and special delivery would save more than 50 per cent of the cost of the milk to the consumer. This would involve in addition a hidden source of cost which arises from the public inspection of the quality and cleanliness of milk as delivered.

Dr. Leary discusses at some length the vitamine content of dried milk preparations. Fat-soluble A is highly resistant to heat, though not to oxidation, and is retained apparently in large part by either method of drying milk. Water-soluble vitamine B is relatively insensible to heat, but susceptible to oxidation. It is not seriously affected by drying, and in the storage and handling of milk powder the loss of this vitamine should be very small. There is, however, ground for debate concerning the antiscorbutic vitamine, Water-soluble C. It is to be kept in mind in this connection that raw milk is not to be considered as necessarily having potent antiscorbutic qualities. Evidence from the clinics is unanimous as to the absence of scurvy on a diet of dried milk. Dr. Leary expresses the belief, however, that no diet should depend upon milk, raw or dried, for its antiscorbutic element, but that this substance should be supplied from sources known to be rich in it, such as orange juice.

## Dried Milk Used As Food

THAT the physician should know all of the facts with reference to as important a food as milk and should be the educator of the community with respect to the efficiency and advantages of methods used in its preservation is the opinion expressed through the pages of the *Boston Medical and Surgical Journal* by Dr. Timothy Leary, professor of pathology, Tufts Medical School, Boston. Further, on the basis of demonstrated fact the physician should be the advocate of drying as a method of preserving milk which, if universally adopted, would make as important an advance in prophylaxis as typhoid inoculation or diphtheria toxin-antitoxin injection. He should know the limitations of the process, however, and should not recommend as the exclusive food of a nursing, reconstructed milk from milk powder without the addition to the diet of an antiscorbutic agent, such as orange juice. He should further recognize that the reconstructed milk is as good a culture medium as fresh milk, and should therefore be prepared only at the moment needed, and with rigid precautions as to cleanliness.

It is evident from the findings reported by Dr. Leary that milk drying should do away almost completely with pathogenic bacteria present in the milk when drawn, e.g., strepto-

cocci, and general use of dried milk should do away with this type of milk-borne epidemics. Mechanical devices should also be possible which would prevent any possibility of recontamination by handling. The average bacterial count of daily samples of reconstructed milk from all of the plants of the principal spray-drying milk companies in the world last year was six thousand bacteria per cubic centimeter. This is the count of highly certified milk. The changes produced in milk by powdering are: (1) Slight loss in acidity. (2) Soluble salts of calcium are converted into insoluble salts, affecting the action of rennet. (3) Lactose is unaffected. (4) Albumin and globulin are partly coagulated. Caseinogen is not coagulated, but all observers seem to agree that it is more digestible after heating. (5) Chemical changes in the fats are slight; possibly a slight degree of oxidation occurs. The lecithins are altered, but little is known as to the exact changes. The fat globules of reconstituted milk are generally larger than those of fresh milk. (6) Ferments are destroyed. (7) As to the

# Dioxogen = (Hydr. Diox.) Oakland

*H<sub>2</sub> O<sub>2</sub> 12v*

STUDY and practical experience have demonstrated that hydrogen peroxide manifests its maximum efficiency, only when it is free from those impurities which interfere with the prompt and unrestrained liberation of the pure oxygen, on which its action depends.

## Dioxogen

therefore, is universally recognized as the best and most effective peroxide of hydrogen, not alone because of its greater volume of available oxygen, which far exceeds U. S. Phar. requirements, but particularly because of its exceptional freedom from residual substances which would restrain in any way the free release and full effects—of this all-important constituent.

The value of oxygen as a purifying and antiseptic agent is too well established to require extended comment; its influence on disease germs, morbid processes, and its stimulation of granulation and tissue repair are so well understood, that further statement is unnecessary.

In a word, Dioxogen offers a means whereby a large amount of pure, uncontaminated oxygen may be brought directly to the places where it is required and in the active condition necessary to assure its highest potency.

NEW YORK CITY

## FROM THE FIELD

A conference on health education in the preparation of teachers, called jointly by the U. S. Bureau of Education and the Child Health Organization of America, will take place at Lake Mohonk, New York, June 26—July 1. Invitations to one hundred education and health workers especially interested in the subject have been issued.

The First International Congress on Mental Hygiene was held in Paris, June 1-4, under the auspices of the French League for Mental Hygiene and Prophylaxis. The program included among other subjects, mental tests for applicants for work, psychology as applied to education, and international agreement for research work in mental hygiene, and mental hygiene in the family.

At the sixth annual meeting of the American Congress on Internal Medicine held at Rochester, Minn., the following officers were elected for the coming year. President, Dr. Sydney R. Miller, Johns Hopkins University Medical School, Baltimore; vice-presidents, Drs. Henry S. Plummer, Rochester, Minn., and Stuart R. Roberts, Atlanta, Ga.; treasurer, Dr. Clement R. Jones, University of Pittsburgh, and secretary general, Dr. Frank Smithies, Chicago.

The National Society for the Study and Correction of Speech Disorders will hold its annual meeting as an allied association with the National Education Association in Boston, July 3-7. Former papers by officers and Massachusetts teachers of speech and ten five-minute papers open to general discussion will form the program for each afternoon. Demonstrations with maps and charts of the progress of the movement from coast to coast will be shown.

The Maryland Bureau of Child Hygiene to be organized in accordance with provisions of the Sheppard-Towner law and legislation passed by the last General Assembly of Maryland will start with a personnel consisting of a director and ten graduate nurses under plans formulated by Dr. John S. Fulton, Secretary of the State Department of Health. Headquarters will be in Baltimore.

Dr. Louis I. Dublin of the Metropolitan Life Insurance Company, New York City, gave an address May 18 before the Boston Association of Cardiac Clinics at the Children's Hospital, Boston. His subject was "Heart Disease in the Community." Dr. Paul W. Emerson of Boston also spoke on "Heart Disease in the Schools."

The South Carolina State Board of Health is furnishing toxin-antitoxin free of charge to all county health departments that are establishing free clinics at rural schools. In Charleston County alone, 2,500 toxin-antitoxin inoculations have been given since January.

The American Pediatric Society elected the following officers at its thirty-fourth annual meeting at Washington, D. C., May 1-3: President, Dr. L. Emmett Holt, New York; vice president, Dr. William W. Butterworth, New Orleans; secretary and treasurer, Dr. Howard Childs Carpenter, Philadelphia; recorder and editor, Dr. Henry L. K. Shaw, Albany, N. Y.; member of the council, Dr. W. McKim Marriott, St. Louis.

A special unit has been established at the Chicago office of the U. S. Veterans' Bureau, with a consultant and an assistant to handle cases pertaining to public health, which not only includes physicians and dentists, but also students desiring to enter colleges of medicine, dentistry, or pharmacy, hospital nurses, trainers desiring courses in roentgen-ray work, laboratory technicians, those desiring special courses in chemistry, biology or pathology, and similar branches including also osteopathy, optometry, and physiotherapy.

At a meeting of the governors of the Institute of Medicine, March 24, a committee was appointed to make recommendations concerning medical needs of Chicago. The committee reports the following needs: Study of concrete medical needs; need of certain classes for better hospital care; need for promotion of medical jurisprudence in its various phases, and the need for a better publicity and education in respect to medical matters. The committee also recom-

mended that small committees be designated from fellows of the Institute to study particular problems and to report their results and recommendations to the governors; further, that the board of governors support the work now recommended by such financial aid as may seem necessary to secure the most desirable results.

Teachers of special classes for feeble-minded and backward children from all parts of Pennsylvania met at the University of Pennsylvania to work out from their own experience a program for statewide care and training of feeble-minded children.

Ontario Health Officers' Association held its eighth annual conference May 29 and 30, 1922 at the University of Toronto, under the presidency of J. W. Shaw.

At the annual meeting of the American Public Health Association held recently in Washington, D. C., the governing council appointed a general committee to reorganize the association after a majority of its members agreed with Dr. L. I. Harris, New York, that the Association was led and directed by corporate agencies in increasing numbers. The first meeting of the committee was held May 4, in New York. Other committees will meet throughout the country and the results will be compiled and placed before the next annual meeting.

The Eighth National Exposition of Chemical Industries will be held this year in the Grand Central Palace, New York City, during the week September 11-16 inclusive. Charles F. Roth and Fred W. Payne, Grand Central Palace, New York City, are managers.

B. E. Read, of the Department of Pharmacology, Peking Union Medical College, has published the minimum drug equipment suggested for country dispensaries in the *China Medical Journal*.

The Department of Public Health has established at the Philadelphia General Hospital five clinics, genitourinary, heart, prenatal, neuropsychiatric, and radiological, to meet the need for the care and treatment of cases which do not require bedside care, and for the purpose of preventing certain diseases by the early study and correction of physical defects. A medical social service department follows the cases closely.

# 4 MONTHS' RESULTS

A Springfield (Mass.) woman suffered from flat feet and bunions caused by wearing narrow-toed shoes. A local doctor advised her to wear

## GROUND GRIPPER WALKING SHOES

She did, and he kept careful diagrams of her feet from April 19th to July 10th. The above drawings are reproduced from his records. They speak for themselves.

"GROUND GRIPPERS" are the ORIGINAL muscle-developing health shoes for Men, Women and Children. They are universally recommended by physicians and surgeons. Instead of imprisoning arches and toes, they flex naturally with your feet in every part—at every step. Nerve pressure is relieved—stagnant circulation quickened—weak muscles strengthened—painful swellings reduced—deformed bones straightened. Feet are completely restored to normal shape, vigor and comfort. And these results are permanent.

"GROUND GRIPPERS" are imitated but never duplicated

## Promoting Health and Hygiene with the Acme

INDUSTRIAL physicians, head nurses, welfare workers, and business executives, who are engaged in educational work, all testify to the excellence of the "ACME" PORTABLE MOTION PICTURE MACHINE. With it they are vividly showing the results of ignorance and bringing about the better living conditions that come with proper knowledge.

The "ACME" PORTABLE is compact, neat-looking, and light. It carries like a suit-case, all set up, ready to go. Just plug in on any light socket, direct current or alternating. Framing and focussing is instantaneous—pictures are clear, brilliant, and steady. Takes

standard reels. Operation is extremely simple—all adjustments are made from the outside. With the Special Acme generator, the outfit may be effectively operated from any automobile.

CARRIES LIKE A SUITCASE

If you are interested, just send in the coupon for complete details. There will be no obligation incurred.

Acme Motion Picture Projector Co.,  
Industrial Service Dept. 64,  
806 W. Washington Blvd., Chicago, Ill.

Without obligation to me, please send me your illustrated folder, giving complete details about the "ACME" PORTABLE. It is understood this inquiry incurs no obligation.

A provisional committee has been formed in England consisting of Sir Norman Moore, president of the Royal College of Physicians, Sir Charles Sherrington, president of the Royal Society, Sir John Goodwin, director-general of the Army Medical Service, and Sir George Newman, principal medical officer of the ministry of Hygiene. This will be similar to the American Committee for Mental Hygiene.

Acquisition and construction of rest camps in the various districts of the U. S. Veterans' Bureau for disabled war veterans are provided for in a bill introduced into the House of Representatives by Representative Gallivan. Five million dollars is appropriated to cover the cost of the undertaking under the jurisdiction of Col. Charles R. Forbes, director of the U. S. Veterans' Bureau.

The French Ligue d'Hygiène Mentale held a congress at Paris, June 1-4, 1922, at the Hotel des Sciences Savantes, 28 Rue Serpente. This served as a preface to the first International Congress of Mental Hygiene which is being arranged to convene in the United States under the auspices of the New York Committee of organization of the League for Mental Hygiene in America.

A new \$30,000 health center is to be built in Alameda, Cal., under the auspices of the board of public utilities. It will be completed in September. Funds for this purpose will be taken from the surplus of the municipal electric light system.

The American Psychiatric Association held its seventy-eighth annual meeting at Quebec, Canada, June 6, 7, 8, and 9, in the Parliament Building and Hotel Chateau Frontenac. Albert M. Barrett, M. D., of Ann Arbor, Mich., is president of the Association.

The Illinois State Department of Public Health, with the approval of the Board of Public Health Advisors, has adopted a Railway Sanitary Code. The Code regulates the transportation of persons having communicable disease, the water and ice supplies for railway trains, stations, offices and shops, the cleaning and disinfection of cars, the sanitary condition and control of cars while in service, and the sanitary conditions at railway stations, railroad construction camps, offices and shops.

A joint committee of men and women representing the medical and teaching professions has been formed in England to inquire into the present physical education of girls with particular reference to its results beneficial or harmful either during girlhood or in later life. Dr. G. F. Still is chairman. The bodies represented are: Royal College of Physicians, London; Royal College of Surgeons of England; British Medical Association; Medical Women's Federation; British Association for Physical Training; Ling Association; National Union of Women Teachers; Association of Assistant Mistresses in Secondary Schools; Private Schools Association, Inc., and the College of Perceptors.

The Congress of Radiology and Physiotherapy was held in London, June 7-10, under the presidency of Sir Humphrey Rolleston and under the auspices of the section of electrotherapeutics of the Royal Society of Medicine and the British Association for the Advancement of Radiology and Physiotherapy. Dr. Beclere, Paris, Dr. Murdoch, Brussels, Dr. Peremans, Antwerp, and Drs. Colombier and Tribout, Paris, will be among the speakers.

The Chamber of Commerce of the United States is sending to its 1,400 member organizations a school health and physical education report.

Dr. Mary Moore Hoyt has been appointed director of nutrition work at the Tuberculosis Association of Rochester and Monroe County, New York.

The curative workshop for convalescent patients conducted by the Tuberculosis Association of Rochester and Monroe County, New York, has attracted wide attention. Credit for the success of the project has been given to Miss Elizabeth K. Wise, director of occupational therapy, and to Mrs. Ruth B. Harter, director of occupational therapy for the State Committee on Tuberculosis and Public Health.

"Life Insurance Laws of 1921" in volume form is now being mailed to companies who are members of the Association of Life Insurance Presidents. The volume contains the laws relative to life insurance passed in the States and Canada.

Henry S. Dennison, president of the Dennison Manufacturing Company, has been appointed by Postmaster General Hubert Work to the office of Welfare Director recently relinquished by Dr. Lee K. Frankel of the Metropolitan Life Insurance Company. Mr. Dennison is well known as a pioneer in the introduction of industrial welfare methods which are both humane and efficient. Dr. Frankel is retained in the Department in the capacity of advisory welfare director.

The Davenport Bill for "safeguarding motherhood and protecting the health of infants and children." recently made a law in New York, converts the existing Division of Child Hygiene into a Division of Maternity, Infancy and Child Hygiene, and makes available for its use (together with the amount in the regular appropriation for the Child Hygiene Division) the sum of \$160,000. This is approximately the amount which would have been made available if the State had accepted the provisions of the Sheppard-Towner Act. The functions of the new Division include the following: Making surveys and studies of local conditions affecting the health of mothers and children; giving advice to different localities as to providing adequate care for mothers and children to whom such care is not otherwise available; holding health consultations in the rural districts; educational work in the hygiene of maternity and infancy; supervision and training of midwives; prevention of blindness in infancy; and care of crippled children.

Women who work with their hands for their living will again be students at Bryn Mawr College this summer at the second term "for women in industry." The school last year had an enrollment of 80, and for the term this summer, from June 15 to August 10, applications of 100 candidates were accepted. Garment and textile workers have the largest representation in the list of accepted candidates. There are nineteen garment workers and fifteen textile workers. Other trades represented are: Telephone workers, seven; electrical workers, six; tobacco and cigarettes, six; printing, five; shoes, five; millinery, three; gloves, two; manufacturer of typewriters, two; watches, two; laundry, two; neckware, corsets, metals, candy, kodaks, automobiles, paper boxes, bleachery, chemicals and soap, one each.

# LOESER'S INTRAVENOUS SOLUTIONS

INTRAVENOUS INJECTION IS A  
SERIOUS PROCEEDURE THAT REQUIRES

**FIRST:** Selection of Standardized Solutions, from a Reliable Laboratory.

**SECOND:** Full Knowledge of the Contents of the Solution.

Half secret compounds, unscientific gunshot combinations, specialties and low priced substitutes are out of place in intravenous medication.

Loeser's Intravenous Solutions are not "cures" or "specifics," but simple scientific solutions of U. S. P. and standard remedies of established therapeutic value. The contents are plainly stated on the label, free from ambiguity, mysticism and charlatanism. They are standardized by chemical, physical and animal tests.

*Clinical Reports, Reprints, Price Lists and "The Journal of Intravenous Therapy" will be sent to any physician on request*

## NEW YORK INTRAVENOUS LABORATORY

100 West 21st Street

NEW YORK, N. Y.

*Producing Ethical Intravenous Solutions  
for the Medical Profession Exclusively.*

# Arhovin

No matter what your favorite local treatment in Gonorrhoea and its complications, you can render it more *promptly* and more *permanently* effective by supporting it with internal Arhovin medication.

For over fifteen years, Arhovin has successfully taken the place of santal oil and balsams in the practice of a host of specialists and general practitioners, because it does not irritate the stomach, or kidneys, nor impart a tell-tale odor to the breath.

Furnished in tins of fifty capsules, each 4 minims.

Dosage: One or two capsules, three to six times daily, after meals.

*Information, Sample and Literature from*

**Schering & Glatz, Inc.**  
150 Maiden Lane NEW YORK

## Recreation Camps and Open Air Schools *Read this message!*

**T**HE summer season has opened and many camps and schools find themselves without the necessary personal weighing equipment. The necessity of weighing regularly to determine the progress of health measures is too well recognized to stress its importance here. You will need one or more scales while the season advances, so why not act now?

We will gladly send you description and prices by return mail on scales that will fit your particular requirements most efficiently. In writing please state whether you desire a scale for indoor or outdoor use. Do not delay, address

### Continental Scale Works

Dept. N—2124 West 21st Place Chicago, Ill.

A municipal maternity dispensary has been organized, maintained, and operated by the Los Angeles Health Department. This Service was made necessary by an increasing number of requests that some provision be made for the care of needy women at the time of their confinement. In 1915 the City Health Department organized the maternity service as one of the divisions of the Department, with the stated object of "providing competent medical attendants for the care of needy mothers during pregnancy, labor, and until mothers no longer need our services."

A national organization for the prevention of accidents was formed in New York City last month. Dr. Franklin Lawson, 7 West Forty-second Street, New York City was elected president and administrative director. Dr. Clayton Powers Bennett and Arnold A. Schwartz are vice presidents; Charles F. Hammond, secretary and Kenneth Patterson, assistant treasurer. The honorary advisory board is composed of Dr. Joseph M. Bennett, Providence, R. I.; Walter C. Carter, C. Arthur Clark, Jr., James B. Clews of Henry Clews & Co.; Frederick Cook, Secretary of State of Massachusetts; Dr. Colis S. Carter, New York; Robert Fisher, Boston, Mass.; Dr. D. H. M. Gillespie, accident surgeon, New York Central Lines; Eugene C. Hultman, Boston; Senator Frederick Hale of Maine; Senator Henry Wilder Keys of New Hampshire; Dr. Russell McCausland, Boston; Norris Oliphant of James H. Oliphant; Theodore Roosevelt, Assistant Secretary of the Navy; Senator Thomas J. Walsh of Montana, Senator David J. Walsh of Massachusetts. The charter of the organization has been approved by Supreme Court Justice Bijur and granted by the State of New York. It was filed in the County Clerk's office on May 1. The society will study the mental and physical causes of all kinds of accidents and the various ways and means of preventing and avoiding them, and will spread this knowledge through its members and the various channels of nationwide publicity, including the press, screen and radio.

"Comparative Antiscorbutic Values of Milk," a review of the literature by J. M. Johnson, Chemist, and C. W. Hooper, Pathologic Physiologist, United States Public Health Service appears in *Public Health Reports* for April 28.

The Technical Photographic and Microscopical Society was fully organized at a meeting held in the Chemists' Club, New York, May 10. James McDowell, of Sharp & Hamilton Manufacturing Company, Boston, was elected president; John H. Graff, of the Brown Company, Berlin, N. H., and Bennett Grotta, of the Atlas Powder Company, Tamaqua, Pa., were chosen vice-presidents, while Thomas J. Keenan, editor of *Paper*, 251 West Nineteenth Street, New York, was elected secretary-treasurer. An active committee on membership and publicity was appointed consisting of A. E. Buchanan, chairman; Charles N. Winter, D. H. Killefer, Douglas G. Woolf, Ernest Eberhard, J. A. Scheick, and M. D. Crawford.

The Bureau of Nursing Education of the Wisconsin State Board of Health is endeavoring to spread knowledge of the necessity for all nurses practicing in that state as graduate nurses to possess a re-registration card issued by that office. The new nursing education law requires an annual re-registration by such nurses to make their practice legal. It is specifically required that all who work as trained, graduate, certified or registered nurses shall hold a certificate from the State Board of Nurse Examiners. The attention of nurses, especially the older graduates, is called to the fact that if their certificates have never been recorded with the county clerk they should do so at once, as the holders cannot be called registered until the law has been complied with. All registrations expire on December 31 of each year.

The report of the examination of fifty males by William Finkelstein and Jesse F. Williams, New York, as to their circulatory efficiency by the Schneider test and as to their physical efficiency by the Sargent test in an endeavor to determine the existence of a correlation is contained in the *Journal* of the American Medical Association. A very definite correlation was found. Though not perfect (perfect correlation = 1), it was high for such diverse tests. The high correlation shows that cardiac efficiency is probably a good indication of general physical efficiency. It will probably be necessary to revise the Schneider test to allow for the normal variation in pulse rate in the age ranges before and during adolescence. The Schneider test was evolved on adults. Its applicability to adolescents and pre-adolescents remains to be determined.

All summer resorts and camps bordering the lakes and streams of Wisconsin are inspected annually by competent men, as to the sanitary condition of such camps according to a report of C. A. Harper, M.D., State Health Officer. Special attention is given to water supply and disposal of garbage and sewage. This work is done in the summer months by the four hotel and restaurant inspectors in conjunction with the sanitary engineering department. The Highway Commission has provided and is making additional provisions for camp sites adjacent to and along all the main highways of the state. Pure wells have been provided; crude stoves are constructed and kindling is provided; facilities are also provided for taking care of the waste from the camp. This has been useful for summer tourists when the camps are crowded. These tourists bring their own tents and cots. Adjacent to many of these camp sites are vegetable stores and some types of grocery stores which are equipped in the summer.

The Associated Out-Patient Clinics of New York City elected the following officers April 6 to serve for the coming year: President, Robert Olyphant; vice-president, Alexander Lambert, M.D.; secretary, Willis G. Nealley, M.D.; treasurer, John Sherman Hoyt. The following were chosen as members of the executive committee: Alexander Lambert, M.D., chairman; E. H. Lewinski-Corwin; Albert E. Lamb, M.D.; Charles F. Neergaard; William P. St. Lawrence, M. D.; Dudley Stetson, M.D.; S. H. Wadhams, M.D.

A new quarterly in the field of general medicine, neurology, and pediatrics, *Medicine*, made its debut May, 1922. The periodical is being edited by David L. Edsall, Harvard Medical School, John Howland, Johns Hopkins Medical School, with Paul D. White, Massachusetts General Hospital, as associate editor. Williams & Wilkins Company, Baltimore, are the publishers.

Dr. George A. Dame, director of the Florida Bureau of Communicable Disease, is making, through the division of field service, brief surveys of each county, covering about 150 physical, sociologic, and sanitary questions that frequently arise in the directing of public health activities in the state.

**AMERICAN**  
THE PRODUCT OF SPECIALISTS

## Surgeon's Office Outfit

THE Surgeon investing in "AMERICAN" Sterilizers, whether for office use or hospital installation, buys with that equipment four distinctive attributes: Prestige, Quality, Economy and Durability.

In our Surgeon's Office Outfit is embodied the same "AMERICAN" standards as the larger types, with the added advantages of compactness and greater economy in operation.

Consists of 8-gal. Water Sterilizer, 10"x20" Dressing Sterilizer, 6"x9"x18" Instrument Sterilizer and 2½ gal. Distilled Water Attachment. Can be furnished for gas, steam, kerosene or electric heat.

Write for bulletins of the complete "AMERICAN" line.

### AMERICAN STERILIZER COMPANY

New York Office:  
FIFTH AVE. BLDG., 200 FIFTH AVE.

"AMERICAN"  
Surgeon's Office  
Outfit, Electrically Heated.

## Radiant Light and Heat for Infected Wounds

Discussing the usefulness of Radiant Light and Heat in his book "Medical Electricity and Roentgen Rays," Doctor Sinclair Tousey says:

*"They induce hyperemia and increase the number and activity of the phagocytes, and in this way they are valuable for local infections.*

*"Before suppuration they may hasten it if it is inevitable, and after suppuration they may hasten resolution.*

*"Infected, sloughing and sluggish wounds are successfully treated by ordinary incandescent light applied over a dressing wet with boric acid solution and covered with rubber cloth, and good results are obtained after laparotomy for appendical abscess, perforated gall-bladder; also in tuberculous and gonorrhoeal joint infections, carbuncles and furuncles, x-ray burns and frozen extremities."*

## Thermolite

### Light and Heat Applicator

A scientifically designed and well made applicator that reflects a flood of strong PENETRATING heat and light in PARALLEL rays—no focal spot to burn or blister.

Far superior to ordinary hot applications because the heat penetrates deep into tissues, is constant, always ready, acts quickly and is combined with beneficial light.

#### USED IN ALL GOVERNMENT HOSPITALS

Try THERMOLITE in the Treatment of Neuritis, Rheumatism, Lumbago, Sprains, Stiff Neck, Burns, Ulcers, Carbuncles and Infected Wounds. Sold by electrical and surgical supply dealers. Write for interesting and instructive literature.

#### NO. 0670 OFFICE APPLICATOR

Reflector 12 in. diameter. Stand adjustable from 57 in. to 96 in. high. Consumes 375 watts at 120 volts A.C. or D.C. Covers area 300 square inches at 36 in. from reflector. Finish: Olive green and nickel. Price: Complete with stand, \$30.00.

#### NO. 0645 HAND APPLICATOR

Same design as 0670 only 8 in. diameter. Consumes 200 watts at 120 volts A.C. or D.C. Made of aluminum; weight 16 oz. Finish: Black and nickel. Price: Complete without stand, each \$10.00. Folding Stand for No. 0645, each \$6.00.

H. G. McFADDIN & CO.  
44 Warren St., New York

(Makers of Lighting Devices Since 1874)

## Vocational Rehabilitation Conference

The First National Conference of State Workers in Vocational Rehabilitation of Persons Disabled in Industry or otherwise, met at Hotel Statler, St. Louis, Mo., May 15, 16, 17, 1922. Workers attending the conference are, from left to right, bottom row: Robert H. White, Leonard B. Job, L. J. Clayton, George E. Horton, D. W. Rokey, H. B. Cummings, C. H. Schopmeyer, Chas. W. Briles, George W. Redvis, J. C. Wright, John A. Kratz, Herbert A. Dallas, H. L. Stanton; middle row: Claude H. Anderson, Alice K. Bough, Lillian H. Davis, Davis M. Cangney, J. R. Jewell, C. A. Fulmer, C. W. Woodruff, H. Harvey, B. R. C. H. Saylor, W. J. Moore, O. M. Sullivan, Kenneth O. Snortum, E. E. Brackett, D. F. Burton, John F. Moore, John C. Shaw, Lloyd A. Henry, Robert O. Small, F. E. Laud. Top row: Ervine Meyer, Sam. E. Woods, F. J. Hubbard, C. M. Le Bow, Marguerite M. Lison, Mrs. Mary S. Barker, Willis W. Grant, W. F. Shaw, Ernest L. Schneider, M. F. Faukes, Mary Anderson, Tracy Copp, S. S. Riddle, Joseph Spitz, F. T. Struck.

## Wells: Chemical Pathology

Chemical Pathology by H. Gideon Wells has established itself as a classic, and the new edition should be welcomed by everyone. The book can be considered the pioneer work in this field and should be on every physician's shelves. In the new edition many of the chapters have been brought up to date and special attention can be called to the one contributed by Woodyatt on "Carbohydrate Metabolism." It is a great pleasure to note the full bibliography appended to each chapter and the excellent index.

W. B. Saunders Company, Philadelphia, 1920.

## American Child Hygiene Association

This volume constitutes a report of the transactions of the eleventh annual meeting of the American Child

Hygiene Association held in St. Louis, October 11 to 13, 1920. It contains a number of valuable papers on various phases of child welfare by workers in the field. The discussion of the papers is at times as illuminating as the papers themselves.

## Psychoanalysis in the Service of Education

A series of lectures by Oskar Pfister, a Protestant clergyman of Zurich, brought out in the form of a book for educators under the title "Psychoanalysis in the Service of Education," deals with the value of psychoanalysis as a method of freeing the autonomous personality from inner inhibitions and extending the field of conscious control. He is enthusiastic in his treatment of the subject, but presents a good case and his book has great practical value.

Though there might be some

reservation as to whether psychoanalysis belongs to the province of the physician or the pedagogue, Pfister is convinced that "teachers are the very men for this undertaking." Direct analysis of healthy children, he says, lies entirely in the domain in which the educator alone has the responsibility. He does not, however, advocate analysis of a sick child without the permission of a medical man, preferably one versed in psychoanalysis. His charge that "most physicians, on account of their one-sided physiological and materialistic training and orientation, on account of their total ignorance of mental processes, are usually highly unsuited for the treatment of the so-called psycho-neuroses," would scarcely appear tenable in view of the magnitude of the literature on the subject at the present time. If the success of the method depends upon a broad view of the "life-totality of analytic subjects," physical as well as psychic factors are involved. If an acknowledged therapeutic measure is to be turned over to educators, some standard of practice and of efficiency would seem to be called for.

Moffat, Yard & Co., New York, 1922.

## Books Received

- THE MECHANICS OF THE DIGESTIVE TRACT.** By Walter C. Alvarez, M.D., Assistant Professor of Research Medicine, University of California Medical School, Octavo, extra cloth, pp. 192. Paul B. Hoeber, New York, 1922.
- PROTEIN THERAPY AND NON-SPECIFIC RESISTANCE.** By William F. Peterson, M.D., Associate in Pathology, University of Illinois, College of Medicine, Chicago, Ill., 307 pp. The Macmillan Company, New York, 1922.
- TOWN THEORY & PRACTICE.** By W. R. Lethaby, Raymond Unwin, George L. Pepper, Sir Theodore Chambers, and R. L. Reiss. Edited with an introduction by C. B. Purdom, pp. 136. Benn Brothers, Ltd., London, 1921.
- CHEMICAL DISINFECTION AND STERILIZATION.** By Samuel Rideal, D.Sc., and Eric K. Rideal. Cloth, 8vo, pp. 313. Edward Arnold, London, 1921.

## INDUSTRIAL NURSING

**S**PECIAL qualifications are demanded of the industrial nurse and these qualifications vary in different plants. For this reason care and intelligence must be exercised in selecting a nurse who will meet the conditions in a certain industry and who will likewise be completely satisfied.

This careful service of selection is one of the principle reasons why Aznoe's service is recognized as particularly valuable in securing the proper industrial nurse for a firm and likewise placing the nurse in a position where conditions are satisfactory to her. Where Aznoe's service is used, both the individual and the employer are satisfied.

Let us send you our booklet giving the full details of Aznoe service, which is also available to industrial surgeon and to plants requiring the services of industrial surgeons.

**Aznoe's** Central Registry  
for Nurses  
30 N. Michigan Ave., Chicago

# Rebuilding The Man

You are frequently consulted by men who have shot their physical and mental bolt.

You prescribe and lay out a well-arranged course of treatment—in fact do everything that scientific skill can do. In most cases the difficulty is that the patient, though his intentions are excellent, is unable to maintain the regimen laid out for him.

You may recommend a change and rest. The watering places, with their gay social life and travel, with its attendant burdens, do not bring rest, which is what the system craves and what you desire he shall secure.

A change to be most beneficial, must be complete—not only change of scene, change of habits, thoughts, diet, occupation, but in short a radically different mental and physical environment.

## Brown's Physical Training Farm

With its perfect equipment and ideal surroundings, affords just the change.

A 300-acre farm upon the bluffs opposite and overlooking West Point assures a high elevation with a restful scenic view.

Fresh vegetables, fruits, and other produce from the farm, and milk from a herd of registered tuberculin-tested Jersey cattle, bountifully supply the table.

A well-equipped Gymnasium, with steam baths, tennis courts, hand ball courts, horse back riding and swimming, are all a part of the regimen at this farm in bringing your patient back to normal.

A Manor House, especially constructed, offers accommodations in individual rooms. The training and physical upbuilding is under my personal supervision, and I solicit correspondence with physicians having cases requiring rejuvenation.

Send for booklet, *Rebuilding the Man*, containing detailed information as to cost, and reference from leading physicians as to my work.

## National Child Health Council Issues Report

The first report of the National Child Health Council is issued in the form of a pamphlet entitled "For the Child." Formed in March, 1920, the National Child Health Council was a pioneer effort in the field of national coordination. The Council was formed of three organizations whose work is distinctly with children—The American Child Hygiene Association, The Child Health Organization of America, and the National Child Labor Committee—and three whose work of necessity concerns itself largely with child health—the American Red Cross, the National Organization for Public Health Nursing, and later, the National Tuberculosis Association.

It is too early for this report to be the annals of achievement, but the several committees are at work on legal, educational, nutritional, and general advisory matters having to do with the complete and economical handling of child health conditions all over the country. A practical demonstration is under way in Mansfield and Richland County, Ohio, to test in practice what may be considered as essential for complete service to

children, its cost, and its potential benefits. Meanwhile plans are under way to survey the field and marshal the facts for future planning. On the whole the enterprise may be considered a truly scientific effort to take care of the child, and its progress report reflects great credit to the vision of Courtney Dinwiddie as Executive Secretary and the other members of the executive organization.

## Bacteriology by Estelle D. and Robert E. Buchanan

"Bacteriology," by Estelle D. and Robert Earle Buchanan is a very simple, elementary one but probably fulfills its purpose as an introduction to bacteriology for students in home economics courses.

One cannot help but feel that the first hundred pages in all textbooks of bacteriology are wasted as they all give the same fundamentals in the same way. Students could all be referred just as well to bacteriological textbooks of ten or twenty years ago and these one hundred pages devoted to the newer bacteriology. This is especially true of the textbook which is being reviewed.

The Macmillan Company, New York, 1921.

## The Life of Jacob Henle

Until recently medical history was written, as a rule, in dry incoherent style. It seems to have been the prevailing opinion among medical men that medical history like medicine itself must be scientific in that it must be chronological, a series of dates and facts with no human action in it.

Victor Robinson is one of the few medical historians who combines medical facts with human action and who views the subject under discussion not as an isolated fact or person but as a part and parcel of human activity in a historical development. This is evident in his book "Pathfinders of Medicine." It is strongly evident in his "Don Quixote of Psychiatry" and this is again evident in "Jacob Henle." Not everybody likes that type of historical writing. Most readers like to read something correct as to facts and written in a literary and human style as well.

Jacob Henle was a great anatomist. He was, in addition, however, also a literary and musical genius and led a highly romantic life. Victor Robinson should be complimented on drawing a picture of Jacob Henle, the scientist and man.

Medical Life, New York, 1921.

## Nourishing Food

Vigorous, healthy children, made so by the use of Hemo, are a delight to all.

## HEMO

for girls and boys in school. A nourishing luncheon or an inviting between meal drink.

Hemo is well adapted for use wherever delicious, sustaining malted food drinks are desirable. SCHOOLS, COLLEGES, PUBLIC HEALTH and INDUSTRIAL WELFARE DEPARTMENTS, Y. M. C. A.'s, Y. W. C. A.'s, we invite your correspondence.

Sample sent free upon request.

## Diseases of the Ear, Nose and Throat in Childhood

Medical and lay people are used to textbooks on the diseases of the nose and throat in large voluminous books written in very technical language. This is why the average nurse or social worker knows very little about the hygiene or diseases of the ear, nose, and throat. Still it is important that any one who deals with children know something about it.

Douglas Guthrie, M.D., has performed good service by writing a simple and comprehensive book on the subject. In it he gives the anatomical, physiological and pathological facts that are most essential to physicians, nurses, and social workers. The physician, as a rule, does not have to go to books of the type written by Guthrie for information, but to the nurse and social worker, this book will be a source of information and enjoyment.

The book is written in a simple and pleasant style. It is in addition illustrated in black and white. The book is to be recommended to any one who seeks reliable information on the subject.

A. & C. Black, Ltd., London, 1921.

## Mentally Deficient Children—Treatment and Training

This book by G. E. Shuttleworth, M.D., and W. A. Potts, M.D., now in its fifth edition, has been a leader in its field since the first edition was published in 1895. The book includes a comprehensive historical review of the subject, and chapters on pathological classification of forms of mental deficiency; etiology, diagnosis, and prognosis; the psychopathies of puberty and adolescence; medical examination of mentally defective children under the regulations of the board of education; the treatment of mentally deficient children; educational training; industrial training and recreation; moral training; results and conclusions.

The appendices include: list of institutions, etc., recognized under mental deficiency acts, and of M. A. B. institutions, institutions in Ireland and British Dominions; list of state public institutions in United States of America; table of speaking exercises; time tables I. C. C. special schools; form of medical certificate under mental deficiency act; Binet-Simon tests of intelligence.

The authors have brought the subject of mental diseases and psycho-

therapy up to date. The illustrations are vivid, many new ones having been substituted for the old. The list of the State public institutions for feeble-minded in the United States has been rewritten and has been supplied by an authority on the subject, Dr. Walter E. Fernald. As far as we know, there is no other book on the subject to rival that of Shuttleworth and Potts.

P. Blakiston's Son & Co., Philadelphia, 1921.

## The Practice of Urology

"The Practice of Urology" by Charles H. Chetwood, M.D., is a text well worth reading. It is pleasingly written and logically compiled; complete and thorough in matters of urology, but carefully avoiding other fields, particularly gynecology.

Throughout the book the author stresses the fundamentals and shuns novelties. He bends toward the conservative and established practices but gives due regard to innovations that have proved worthy of consideration. It is a book that one can read easily and with confidence such as is not often so readily inspired by a textbook.

William Wood & Co., New York, 1921.

## CHILDREN'S SHOES

that are  
*Scientifically  
Designed*

**M**ANY physicians and nurses are accustomed to prescribe Health Maker Shoes for children, because of the scientific care with which they are designed.

Each Health Maker Shoe is built to follow the natural foot contour, to give support where needed, to allow ample toe space, to provide for the proper development of the child's foot at every stage.

The inherent quality in Health Maker Shoes insures long service; the sensible lasts provide for natural and healthful foot growth.

## Popular Misconceptions on Food Poisoning\*

A PHYSICIAN received a phone call at eleven o'clock at night from a young woman, in this particular instance a trained nurse, who told him that for thirty-six hours she had been suffering from violent stomach ache subsequently to eating some unripe fruit. At the onset she experienced nausea and vomiting and immediately took a dose of castor oil, which was followed by some diarrhea. The pain remained very severe but the patient thought it would pass away as soon as the oil had worked. The physician, wise to the ways of patients and to such stories, immediately jumped into his car and rushed over to see the patient. The temperature was only 99½ degrees, the pulse 90, and the abdomen typical of a ruptured appendix, calling for immediate operation. This was immediately done and, since the patient in question was lucky, she recovered.

### Popular Food Fallacies

This is not an unusual experience in the life of any practitioner of medicine. Unfortunately it is a common trait of human kind to trace back any gastro-enterologic disturbance to some food previously taken. It is usual to see acute appendices, gall bladders, or ulcers of the stomach, diagnosed by the suffering patients as being merely some form of food poisoning. It is possible even to encounter self-diagnosed cases of ptomaine poisoning, a disease which practically never exists, and which would better be entirely left out of the minds and thoughts of both physicians and patients.

Food poisoning as such is extremely rare. Occasionally an epidemic of food poisoning occurs, always involving a group of individuals who have partaken of the same food. If, however, a group of eight people eat identically the same meal and a few hours afterward one of them becomes stomach sick, it is quite illogical to assume that the food ingested had anything at all to do with the sickness. The average stomach can handle a great variety of so-called indigestible substances and when food upsets an individual the cause is usually to be sought in the individual, and not in the food. The popular conception that food causes trouble to the individual is based on the psychological desire to find a cause for an effect, and food recently ingested is at once associated with present discomfort. A farmer plants some seed in two adjoining fields and only one of them produces a good crop. He necessarily concludes that the soil of one lot is fertile while the soil of the other is not productive; he does not say that the seed is responsible for the lack of growth in the poor lot. The same principle must be grasped regarding the subject under discussion. Many conditions in the individual may cause food to disagree with him. A man in the pink of physical condition who usually can eat a meal from soup to nuts will find that at the end of a nerve-racking, exhausting day, when his whole system is fatigued, he will not be able to eat such a meal without distress. People who have chronic, growling appendices—which means simply that more or less latent sub-acute appendicitis which once in a while sets up a roar—are subject to attacks of indi-

gestion. One man personally known to us was being treated for intestinal indigestion. He subsisted for years on a very carefully planned diet which made a semi-invalid of him, but became perfectly normal in regard to his food after the removal of a chronically inflamed appendix. Another man, following the type of the nervously fatigued or tired business man, was utterly unable to handle foods properly and was under constant treatment for stomach trouble. This man never knew what exercise meant, paid no attention to his bowels, was in the habit of making business notes in the midst of a meal, and, naturally, did not give his gastro-intestinal tract a fair chance. After he was studied and put on the path of right living, food became a pleasure, and the very things which upset him the previous month were eaten with relish and completely digested after he took up golf.

### Food Fears and Idiosyncrasies

Ulcer of the stomach is at the bottom of many of the so-called food poisoning cases. An ulcer may produce very active symptoms which allow of no mistake in diagnosis. But again an ulcer of the stomach, like a chronically inflamed gall bladder, may produce a train of rather vague stomach and intestinal symptoms which the individual cannot definitely analyze and which makes him fear foods of various kinds. These individuals, if they eat a plate of ice cream or a broiled live lobster, will be distressed and will invariably tell the tale that they are poisoned by certain foods. As soon as the underlying condition is cleared up, food takes its proper place in their lives and, with the exception

\*The fifth of a series of articles on "Popular Medical Misconceptions," beginning with the March issue of THE NATION'S HEALTH.

of certain restrictions made necessary by the disease, they are perfectly happy in their choice and use of foodstuffs.

Enough has been said to emphasize the point that when individuals are affected unfavorably by certain foods, it is usually some fault of the individual and not of the food. When a group of individuals are upset by some food an entirely different condition is present because in this instance there is mass evidence that the same food is disturbing a large number of normal individuals.

What these conditions are need not

be detailed. Epidemics due to infected meat and olives are well known. Careful studies in dietary deficiencies are revealing more and more evidence that such deficiencies may produce states of ill health in groups of individuals. But it cannot be reiterated too often that any individual who says that food of any kind is poisonous or complains of stomach-ache, diarrhea, or other symptoms with reference to the gastro-enterological tract is most likely suffering from a definite pathological lesion somewhere in the body. If the trouble is acute, far and away the largest percentage of individuals

have an acute appendicitis, a gall bladder colic, or an ulcer of the stomach, conditions which call for immediate medical attention. If the underlying condition be acute appendicitis, no one needs to be warned that the knife and only the knife can save life. Therefore it is necessary for both professional men, who are still too willing to accept the patient's diagnosis of food poisoning, and for the individual himself, to assume that ptomaine does not exist and that the incidence of individual food poisoning is as rare an entity as is met with in medical practice.

## Safeguarding Life and Health on Railways

BY RALPH BUDD, PRESIDENT, GREAT NORTHERN RAILWAY COMPANY, ST. PAUL, MINN.

**S**AFEGUARDING public health on the railways of the United States today is a highly efficient procedure strictly confined to the rules of medical science as worked out and standardized under what is known as the United States Railway Sanitary Code.

Previous to this standardization of railway health rules in 1920, the various railways protected the traveling public's health under the health laws of the different states through which they operated. Medical men found an utter lack of uniformity among these laws of the several states and also among the many railways on the subject of sanitary regulations. As a result of this lack of uniformity there naturally was much confusion and there existed a great many obstacles to successful enforcement of rules for safeguarding public health. For instance, in many adjoining states the regulations were in conflict and this made a difficult situation and one quite illogical in many respects. The matter was brought to the attention of all the state and territorial health officials with the result that a committee was appointed and a uniform sanitary code was drafted and approved by the Surgeon General of the United States Public Health Service. The result is that the public is better protected while traveling on railways today than it is in any other place of congregation, theater, church or any other public place not excepted.

The railway sanitary code is federal law. It covers the transportation of persons having communicable disease, maintenance of water and ice supplies in passenger cars, cleaning and disinfection of all railway cars, sanitary safeguards in stations, con-

struction camps, general offices, shops, ticket offices.

The Great Northern Railway may be classed as one of the pioneer transcontinental lines in the matter of safeguarding public health. It became an early necessity for this line to recognize the need of stringent sanitary measures to protect the traveling public as the result of its Asiatic steamship connections on the Pacific Coast.

Employees in the dining car service undergo physical examinations before entering the service and at frequent intervals thereafter. Ice and chill boxes are sterilized at the end of each trip. Food is served in individual containers whenever possible.

The strict lines of health safeguards established by the Hill line years before the standardization of health laws effected by the United States Sanitary Code served as a model for Northwest carriers. While it is true that this condition was due in a measure to the strictness of health laws of the states through which the Great Northern operates, the chief factor al-

ways has been the unflinching sanitary efforts of the Hill line's efficient corps of medical men under the supervision of an exacting surgeon general who early saw the necessity of stringent methods because of health dangers incident to the company's steamship connections with Asiatic ports.

Most of the other transcontinental lines observed sanitary measures just as strictly before the sanitary code was standardized. It was the smaller inland systems that were lax in some respects. But today all the public carriers are operating under this standardized code and the traveling public is equally protected anywhere it goes upon railway trains in the United States.

In other days disease probably was spread broadcast in some instances as the result of an employee or passenger getting on a train with a communicable illness. It is a standing joke today in medical circles that about twenty years ago a colored porter with smallpox gave the disease to people from San Francisco to Chicago and that passengers making eastern connections from his train there carried the disease on to New York City. With the present system of check on communicable disease, such a thing would, of course, be impossible today.

Dining and sleeping car crews today undergo physical examination on entering the service and at frequent intervals thereafter. Sanitary conditions on dining cars are safeguarded by constant application to the subject on the part of all who are connected with the service. Ice and chill boxes are cleaned and sterilized at the termination of each trip. Separate compartments are provided for individ-

The dining car of the Great Northern showing minute attention to cleanliness.

ual foods, one, for instance, containing nothing but fish, another butter, fruits in another compartment, etc. All milk is served in individual bottles and the product is not exposed during its journey from the cow to the consumer. Waiters are clothed from head to foot in clean white linen each time they go on duty. Passengers are provided with clean linen for each and every individual service. The dish and glass washing department is very thorough in every detail, providing positive prevention of communicating disease. All dining cars are equipped with door and window screens to exclude the obnoxious fly. Electric fans in the body of the car distribute the pure fresh air entering through the window screens, assuring comfort on hot days. Drinking water is protected by being carried in tanks that are sterilized at terminal points. Sanitary water pitchers on dining tables exclude all foreign objectionable matter and pure clear ice is used for water glasses.

In sleeping cars the passengers are surrounded with every conceivable protection. There is no contact with anything that is not clean. Three sheets 63x90 inches are placed on every bed. Blankets are laundered and sterilized. Mattresses are vacuum cleaned and aired at terminals. Carpets are swept with vacuum carpet sweepers every day en route. Porters are attired in clean white linen. The drinking water tanks are sterilized at every terminal. Sanitary drinking cups are furnished free. Pure clear ice is handled by porters using ice tongs, never touching the ice with their hands. Lavatories are disinfected daily with germ-killing solu-

tions that destroy and still are not objectionable to the most sensitive person. Wash bowls of German silver are kept scoured and polished and therefore clean at all times. Smoking compartments are cleaned often and thoroughly. Cuspidors are equipped with sanitary fiber lining, these being changed often and therefore are kept clean and sanitary.

During the latter part of 1918 the Great Northern Railroad organized a Safety Section for the purpose of eliminating accidents causing death and injuries to its men and patrons. The Superintendent of Safety of the Great Northern says:

The present Safety committees, serving at each of the division points and in each shop on the system were organized in January 1919. Our com-

mitteemen represent each craft in railroad service. We have 452 men serving on committees which meet once each month at their respective Division points or shops. During the years 1919, 1920 and 1921, these various committees made 7,651 recommendations for the elimination of dangerous practices and conditions, 97 per cent of which have been accepted and put into effect.

Although we have had an increase in business and locomotive miles in the years 1919, 1920 and 1921 as against the year 1916, 1917, and 1918, we have been able to show a marked decrease in the number of persons killed and injured, as following figures will indicate:

76 less employees killed, decrease of 38 per cent  
 3732 less employees injured, decrease of 17 per cent  
 28 less passengers killed, decrease of 100 per cent  
 502 less passengers injured, decrease of 36 per cent  
 73 less outsiders killed, decrease of 32 per cent  
 229 less outsiders injured, decrease of 33 per cent

The fact is generally accepted that a large majority of all accidents are preventable and a large part of them are due to dangerous and thoughtless practices and not to defective machines, structures, and equipment.

It has been the aim of the Safety Department of the Great Northern Railway to impress upon the employees the importance of the attention to duty and we feel that the movement has been successful in no small measure.

In the safety meetings mentioned the employees are encouraged to bring in their complaints; the complaint will be gone over and if the complaint or suggestion is found to have merit, immediate action is taken and the matter is rectified. But if the suggestion or complaint is found to be impractical, the employee is told so and the reasons why. We feel that in

Passengers are surrounded with every conceivable protection on sleeping cars. Mattresses are vacuum cleaned and aired at terminals and carpets are swept with vacuum carpet sweepers every day en route.

Water coolers are cleaned and sterilized at the end of every run. Ice is always handled with tongs and never touched by hands.

this way when the employees see that their suggestions are given consideration by the management it brings a feeling of cooperation.

An analysis of the latest Interstate Commerce Commission figures on the annual accident records of all railroads in the United States prepared by the Committee on Accident Statistics of the American Railway Association shows that fewer people were killed in 1920 than in any year since 1898. Although the total number of employees in the railroad service is several times greater than in 1891, yet the fatal injuries to employees in 1919 and 1920 were less each year

than they were twenty-nine years ago. For each passenger killed in railroad accidents last year almost as many as the total population of New York City or five million passengers traveled with complete safety.

On the Great Northern Railroad during the years 1919, 1920 and 1921, or since the inception of our present Safety organization we carried 26,352,582 passengers without a fatal accident. We attribute this in the first place to the careful manner in which the equipment is inspected, and secondly to the vigilance and obedience to rules and regulations by train and enginemen.

## The Rat a Social Menace\*

By CHARLES V. CRASTER, HEALTH OFFICER, NEWARK, N. J.

**A**LTHOUGH there are two main species of rats, the black and brown, the brown rat, often mistakenly called the Norwegian rat, is by far the more numerous and important. The brown rat is really a native of China and his worldwide distribution is the result of successive waves of invasion westward across Europe and finally in merchant ships to America and the Antipodes. Until the year 1727 the black rat lived unmolested in Europe, in which year it is recorded that numerous swarms of brown rats were observed swimming across the River Volga. The reason for the invasion of this rat from Asia was probably the need for a new food supply for the rapidly increasing rat population.

Larger, fiercer and more omnivorous than the black rat, it quickly established itself in Europe and the

British Isles, slaying, devouring and driving the more gentle black rat before it until the latter leads a precarious and uncertain tenure of life in places where the brown rat cannot reach it. Many stories are told of the fierce and ruthless character of the brown rat. Although an herbivorous animal it will eat anything, and when hard pressed for food readily devours its kind.

It is extremely prolific and the rate of increase depends only upon the opportunity for an abundant food supply. When forced by starvation rats will migrate in immense troops in search of food. These migrating hordes are reported from time to time from all parts of the world.

There is also an annual migration of these animals from the cities to the countryside farms and lanes attracted by the green food and presence of smaller game. A return to the cities takes place in the fall when the outside food supply fails.

There is no human foodstuff that the rat will not eat readily and indeed its voracity is extraordinary. Not only is the loss of food stuff for rat sustenance great, but the accompanying destruction of food supplies reaches enormous proportions. Not only foodstuffs of all kinds are ruined but great damage is done to property by the destruction of woodwork, masonry, and plumbing. It is estimated that the total cost for the number of our rat population amounts to one hundred and eighty million dollars per year, or one dollar and eighty cents per person in this country, although indeed, it is calculated that the loss involved represents the constant effort of more than two hundred thousand men to produce the materials consumed and destroyed by rats. It is difficult to estimate the rat population in America, but it is conservative to say there are two or three rats to every person in North America. According to Lantz of the United States Bureau of Biological Survey "the destruction wrought by this vast horde of rodents is far greater than that wrought by lion, tigers, wolves and all other noxious mammals together. The damage done by any species of insect is usually confined to certain geographic limits, rarely extending over large parts of a continent; that done by the rat extends over the whole world."

Not alone from the side of food and property damage is the rat a menace to man but also from the hazards of disease transmission. The relation of the rat to public health was not suspected until twenty years ago when the Indian Plague Commission showed that plague was communicated by means of the rat infected with the disease and by the rat flea which left the body of the dead animal and by means of its bite brought about infection of human beings. It was clearly shown that in all plague epidemics there are existing or preceding epidemics of the disease among the rat population.

### The Rat and Disease

The rôle of the rat in bringing about bubonic plague having been thus firmly established, it is evident that historically it is responsible for more human deaths than all the wars known to humanity. The great plagues of the Middle Ages are now recognized as being bubonic plague. The Black Death which swept across Europe during the fourteenth century was a rat-borne plague, and was responsible for the death of over 25,000,000 of persons. In India, the en-

\*Reprinted by courtesy of the Monthly Bulletin of the Department of Health, Newark, N. J.

demie home of plague, many thousands of persons die annually from this disease.

Rats transmit other diseases besides plague, notably trichinosis and various tapeworms. More recently it has been established that the rodent is responsible for the transmission of epidemic jaundice or Weil's disease.

The infection was common among the troops during the World War and was a consequence of the enormous number of rats that existed in the trenches and dugouts and that carried the infection by contaminating food and food utensils.

Epidemic jaundice has been reported from several States of the Union especially the New England States and New Jersey. An inquiry sent out recently to the physicians of Newark revealed the existence of ninety cases of epidemic jaundice which had been under treatment in three months. It is probable that this number represents only a small portion of the cases actually existing. The relationship of the present prevalence of jaundice to the rat does not require a great deal of proof. It is fair to assume that a similar focus of infection is present in this country as in the case of the battle fields of Europe. In

any case the rat is suspected and becomes a public health menace of even greater importance than formerly.

There is then every reason to call for a war against the rat, not alone for reason of the vast economic loss it causes but as the inciter of disease, pestilence and death.

Although it is virtually impossible to exterminate the rat, steps can be taken for its suppression which will have far reaching results. The main points of attack are the rat's habitation and its food supply. There is a vital need for the rat-proofing of warehouses and stores and the proper protection of food stuffs, so that the rat cannot gain admittance to such supplies.

A building can be made rat-proof, and indeed a whole city may be rendered rat free, if a proper warfare against the pest is carried out. Rats will not thrive where there is not an abundant food supply. Once cut this off and there must be a migration to more suitable location. Rats may be destroyed by three methods, traps, poison and bacterial virus. Of these the first is probably the most efficient if properly carried out.

Properly to destroy the rat it is necessary to know their habits and outwit them. A rat will seldom run across an open space, preferring to run close to a wall. They are cunning and cautious and avoid anything that looks suspicious. They are, however, very curious and will readily enter lengths of pipe and explore dark corners.

The best form of trap is the ordinary spring or guilotine trap which can be bought for ten or fifteen cents. It is better to use the traps unbaited as rats are suspicious of baited traps but readily step on an unbaited one if properly placed. Set several traps along the sides of rooms or the footing of walls. They may be set in a semi-circle around a rat hole or one after another along a rat run. It is better to run six or seven than two or three. It is just as well not to attempt to close the rat holes because they will soon find other ways of entrance unless the building is properly rat-proofed. Diligent trap setting will quickly exterminate all rats in a building.

There are many rat poisons on the market with many and various claims made. Barium carbonate is one of the best of these, made up with flour in the proportion of one to four, and mixed into a thick paste. The objection to the poison method is the possible nuisance of the dead rat on the premises. The viruses have similar objections in spite of the fact that claims are made that the animal will come into the open to die. Whatever method of destruction is adopted it should be persisted in until success is assured. "Man," says Lantz, "has been fighting the rat for centuries and has made little progress. The rodents are entrenched in fortresses of man's own building. If they are driven out or overcome for a time others soon swarm from neighboring premises and the battle has to begin anew. The work has been made abortive by providing continued subsistence for the rodents and by failing to destroy their entrenchments."

There can be no question of the need of a united and constant campaign to eliminate the rat menace. Rat proof building should be the requirement for our dwellings. Rat-proof food supplies in our warehouses and stores. The open garbage bucket in the house and the improper care of offal in slaughter houses and meat stores are constant reserves of food supply for the rat. He will remain only as long as his food supply lasts. Like his fellow pest, the housefly, the existence of the rat depends upon the careless habits and indifference of the average individual. It is indeed time that the rat be no longer tolerated in well kept cities.

# RATS ARE A MENACE!

**KILL THEM! STARVE THEM!**

## DIRT and DESTRUCTION

Rats cost the people of this country \$180,000,000 per year or \$1.75 per person.

One rat eats 50 pounds of grain per year and destroys a much greater amount.

Food is polluted in homes, stores and warehouses by the rats.

## DISEASE and DEATH

Bubonic Plague is spread by rodents, and now we find them spreading Epidemic or Trench Jaundice. Other fatal diseases may be their contribution to society.

## "THE FOUR HORSEMEN" OF DOMESTIC EVIL:

Dirt, Destruction, Disease and Death

## STARVE THE RATS

Do not keep food exposed or in paper, or cardboard containers. Food protected in glass, metal or wooden containers cannot help feed these pests. They will leave before they starve

## TRAP THEM

Set plain spring traps along base of walls where rats run. No bait is needed. Be Careful in handling traps and keep children away.

## POISON THEM

If traps are impracticable use Barium Carbonate mixed with four times as much flour and made into a dough.

**Provide proper Garbage Cans and keep them Covered AT ALL TIMES!**

DEPARTMENT OF HEALTH  
NEWARK, N. J.

The destructive activities of the rat are brought home to the people of Newark by placards of this nature which must arrest the attention and carry the sense of individual responsibility in the matter.

## Knight Mental Deficiency Bill

The Knight Mental Deficiency Bill, introduced by the New York State Commission for Mental Defectives, and passed by the legislature, was vetoed by the Governor. The bill contained a provision permitting magistrates, on appeal of persons having a legitimate interest in the matter, to make temporary commitments for observation of persons appearing to be mentally defective. Under the present law, there is no practicable means by which a mental defective can be committed to an appropriate institution even for the purposes of a preliminary mental observation, except upon the consent and application of parents or of the mentally deficient person himself. The present New York insanity laws have a provision, similar to the one proposed in the Knight bill.

# Child Health Centers in Czecho-Slovakia

## American Red Cross Workers Carry Public Health Message to Bohemia

By FERDINAND O. REINHARD, A.B., M.D., MEDICAL FIELD INSPECTOR, AMERICAN RED CROSS, PRAGUE, CZECHOSLOVAKIA

IN ORDER to give some idea as to the difficulties encountered in the attempt to introduce preventive medicine into an old country where for generations life has been lived according to inherited ideas and established customs, it will be necessary to give a short description of the locality, of the underlying economic factors, and of the general trend of community thought.

One locality chosen for the introduction of a child health center was a small town 7,800 inhabitants, situated in an unfertile valley and surrounded on all sides by the wooded slopes of the Sumava range. The town of Susice has for generations been one of the poorest sections of Bohemia. The farm lands are on the whole unproductive and the large tracts of forests are to this day controlled by a few members of the old aristocracy. As a result the inhabitants depend for their livelihood on the presence of two match factories, one paper mill, and one leather factory.

The salaries paid by these industries before the war ranged from 30 hellers per day for women to 60 hellers for men, while at the present writing 50 to 120 crowns a week covers the earning capacity of the average worker. When we consider that bread which formerly cost 30 hellers a loaf now costs 4 crowns, we realize that relatively there has been no great change in the economic life of the workers. It is of interest to note that at the present time one dollar is worth 54 crowns, and that upon such incomes families of six and eight manage to exist.

Something must be said concerning the racial factors which enter into all work done in the new republic. In this particular section of Bohemia we have a fair example of the intense nationalism so common in Central Europe. The town of Susice is inhabited by a predominant Czech population. Perhaps 90 per cent of the people are Czechs. As a result one rarely hears German spoken on the streets, although it is quite universally understood. However, within one-half hour's ride by automobile we come to villages where the Czech

language is not understood and German signs adorn the streets.

A third factor which enters into all public health work, and which cannot be evaded, is the attitude of the insurance doctors. They are an all-important organization in the Republic of Czecho-Slovakia, chary of their rights, and rather inclined to view with distrust any endeavor which might possibly have a bearing on their source of revenue. Practically all workers are insured by their employers against injury and disease. This insurance in most cases includes the families of the employees. An interesting form of local insurance exists in one of the match factories where pregnant women are allowed seventy crowns a week and are released from work for six weeks preceding and six weeks after childbirth.

### Housing and Illegitimacy

At the present time we have two further disharmonies to contend with, namely, the appalling shortage of houses, with the consequent overcrowding and unhygienic living conditions, and the presence of great numbers of illegitimate children. It

is hardly within the power of social medicine to deal effectively with either of these problems, and yet they underlie much of the misery and disease present in the Central Europe of today.

It was in this community, bristling with difficulties, that Dr. H. O. Eversole, Director of the American Red Cross child health work in Czecho-Slovakia, determined to introduce a health station. It was decided that after a foothold had been firmly established in Susice, the work should be expanded by the addition of rural clinics. These were to be visited one day a week by the personnel of the main center and, if possible, the same routine of examination was to be carried out.

The actual work of establishing a Red Cross health station was invariably done by a graduate nurse and a social service worker. The duties of the nurse were considered to be the supervision of the medical management of the station, the teaching of public health classes, the training of Czech helpers, and home visiting in urgent cases. Besides, it was considered to be her duty to support the

As a part of the routine examination, elaborate social and medical histories are taken of each child. Social workers are shown in the health center at Susice obtaining this valuable data.

Each child brought to the health center is weighed and measured. Aside from helping the individual child, statistics are being compiled for long range study.

local physician in whatever way possible.

The work of the social service worker consisted largely of the management of the dispensary from the technical side—the keeping of accounts, the formation of local committees, and the making of contacts which might be of use in furthering our work. Aside from these duties, volunteers were to be trained by the nurse and social worker both along theoretical lines and by actual home visiting.

#### Personnel of Health Station

It was early decided that the Red Cross stations should be as far as possible consultation centers where advice to the parents would be emphasized while actual medical treatment was to be reduced to a minimum. Relief in the way of food and clothing was to be given only in cases of actual distress, and after a thorough investigation by the social service department had been made. Indeed, relief was to be looked upon as a form of medicine. Furthermore, health propaganda, whenever and in whatever way possible, was never to be lost sight of.

The personnel of a typical station consisted of the following: one local physician, the American nurse, and American social worker, a Czech nurse who would ultimately take over the work, two interpreters, two health visitors, one chauffeur, and besides these, any volunteer workers whom it might be possible to procure.

The preliminary steps toward the

founding of the Susice health station were taken in August, 1921 when a meeting with the Mayor and the local physicians was arranged in order to determine whether Red Cross work in the community would be either desirable or, under the circumstances, feasible. As the result of this conference, three large airy rooms on the ground floor of the poor-house were placed at the disposal of the American Red Cross. Heat, electric light, and running water were to be furnished by the town. In return the Red Cross offered to furnish the necessary supplies and to finance the salaries of the personnel. The next problem which presented itself was to find the best local physician available and, after due consideration, the local school physician was determined upon.

Actual work was begun on September 27th, when the doors were thrown open for the examination and standardization of the children of the district.

The description of a routine examination shows with what care the ultimate aims to be achieved were kept in view, namely, the desire to acquire valuable statistics, while at the same time helping the child by adequate advice, and in isolated cases by the giving of actual relief. In the first place, an elaborate social and medical history was taken of each child. Next, the patient was stripped, weighed and measured. Both the sitting and standing heights were recorded. From this data the pelidisi were calculated according to the formula of von Pir-

quet. Other measurements, such as the circumference of the head and chest expansion were taken for possible statistical use. The child was now considered to be ready for the physical examination. This was done in a thorough routine manner in all cases, and any defects found were entered on the chart. At the end of the examination the parents were advised as to the general health of the child and the necessary steps to be taken for the removal of the defects. Whenever possible children requiring medical care were referred to their respective insurance doctors for treatment. Cases which did not come under this heading were treated at the dispensary and referred to the public health nurse for follow-up work. Where home distress seemed to be the outstanding factor, the social service department was called in for consultation and further investigation.

With the actual functioning of our clinic, local problems naturally arose. In the first place, the insurance doctors became frightened and stated in so many words that if any treatment were given they would oppose any work we might care to undertake. Next there developed a general apathy among the townspeople when they began to realize that relief supplies were given only in isolated instances. It was only with the greatest difficulty that these people were made to see that the ultimate good to be derived from the elimination of removable defects would in the long run be of far greater benefit to the future generation than the temporary well-being produced by the promiscuous distribution of a few supplies.

In spite of these difficulties, the station at Susice has examined 1,296 children to date.

#### Expansion Shows Popularity

Although after three months' work along public health lines one can hardly look for results, nevertheless certain encouraging events have taken place. Scabies and pustulitis, which were exceedingly common on our arrival, are now hardly ever seen at the clinic. This is undoubtedly to be attributed to the home visits, health talks, and actual treatment. Up to the time of writing six villages in the district have made formal requests for health stations. And last but not least, the Ministry of Public Health has been asked to furnish a health officer for the district.

At the beginning of December it was decided that the local clinic was functioning sufficiently well to permit

further expansion. Consequently two mountain villages within automobile distance from the central station, were chosen for weekly clinics. Not only were we welcomed with open arms, but every effort was made to help us make our rural work a success. Except for the fact that the villages of Strasen and Kasperske Hory are both predominantly German, and that more actual treatment is necessary owing to the lack of doctors, the problems do not essentially differ from those found at the main clinic.

An impressive feature of the work in the community under discussion is the fact that on the whole the inhabitants are intelligent and desirous of bettering their condition. Although great numbers of filth diseases were present, it was quite apparent, after some observation, that they were the result of impossible conditions produced by the war and not the outgrowth of personal indifference.

Toothbrush drills at one time became so popular that, after eighty had been gone through with and it was announced that the allowance for the day had been used up, a riot almost ensued. Health classes have been very popular and in some cases courses had to be repeated. At the present time classes in hygiene are being given to health visitors and little mothers. Two classes a week in pre-natal care, with twenty-four and twenty-six members respectively, are being given. Besides these courses, health talks are given once a week to more than one hundred adults at the

country clinics, and every opportunity is made use of to impress the mothers and guardians with the importance of hygienic living.

The impossibility of changing overnight the inherited ideas of generations will be understood by anyone interested in public health work. We cannot hope to eradicate the fear of deadly night air, or the antipathy towards certain kinds of food in a few months. However, in Czecho-Slovakia new ideas are likely to fall on fertile soil and it is only a question of time until lasting improvement will become apparent.

### Same Problems as Elsewhere

It will be seen from this rather sketchy resumé that the work which the American Red Cross is establishing in one community of this new Republic is accomplished only with great difficulty, and that the problems encountered are largely the same as those met with in the United States. The same question of underpayment of public health officials exists. Indeed, the lack of appreciation of this phase of medicine seems to be ubiquitous among the laity throughout the world. As a result, it is impossible to pay physicians adequate salaries, thus making part-time positions a necessity. There is in all countries great danger of political control, with consequent degeneration of positions held by public health officers into "political plums," a condition to be avoided.

Too much credit cannot be given to the Director of the American Red

Cross in Czecho-Slovakia, and to the nurses and social workers of the organization, for their unselfishness and devotion to public service, which made this great work possible.

To appreciate fully the difficulties of the field staff, one must have lived in the distant villages where poor living quarters are the rule, and where unaccustomed food and isolation are ever present factors. Added to these difficulties, we have the problem of transportation. Rural clinics at best are from two to three hours from base centers, and during the winter months the roads are often well-nigh impassable.

After visiting the stations established in upper Bohemia, the writer feels convinced that the opening wedge of public health endeavor has been successfully driven into a virgin soil, teeming with conservatism and ridden by age-old customs and misconceptions. However, only a comparatively short time should be required to build up a modern structure of social medicine upon the foundations which have been firmly laid by the American people through the agency of the American Red Cross.

### Tonsils and Teeth Bother First Graders in Detroit

The physical inspection of 19,533 children of the first grade in the Detroit Schools reveals that 15,755 (81 per cent) have one or more physical defects. Enlarged or infected tonsils are present in 58 per cent of the group. Severe dental defects afflict 24 per cent; 10 9/10 per cent are mouth breathers; 6 1/10 per cent have defects of vision; 4 8/10 per cent are anemic in appearance.

There are 3,778 children, about one-fifth of the total, who have no outstanding defects.

Forty-nine and two-tenths per cent are susceptible to smallpox, having never been successfully vaccinated.

The numbers and percentages of children with each defect are as follows:

Defect	Number of Children	Per Cent. of Total Children
Defective tonsils.....	11,315	58.0
Defective teeth.....	4,684	24.0
Mouth breathing.....	2,127	10.9
Defective vision.....	1,190	6.1
Anemic.....	936	4.8
Lung examination recommended.....	601	3.1
Heart examination recommended.....	533	2.7
Defective hearing.....	361	1.9
Skin eruptions.....	331	1.7
Enlarged thyroid.....	269	1.4
Enlarged cervical glands.....	162	.8
Orthopedic defects.....	152	.8
Deformed palate.....	6	.03

From apathy and even opposition the Red Cross has won over the people to enthusiasm and support of the various health centers.

# Status of Oleomargarine in Nutrition\*

## Laboratory Precision Now Can Safely Assure Constancy of Vitamin Content

BY CASIMIR FUNK, ASSOCIATE IN BIOLOGICAL CHEMISTRY, COLLEGE OF PHYSICIANS AND SURGEONS, COLUMBIA UNIVERSITY, NEW YORK CITY.

**D**URING the eleven years in which I have been engaged in research, mostly in the field of vitamins, this is the first occasion that I have addressed a gathering of business men of one of the great food industries on some of the problems of development and production. This occasion augurs well for closer cooperation between the practical business man representing industry, and the food industry, essentially chemical, in part, and the laboratory man, who can help the former and from whom he can learn a great deal himself.

The margarin industry has been of late distinctly in the vitamin "phase." Being myself a good deal responsible for the development of this branch of nutrition, I am anxious to see what can be done to overcome the difficulties which have recently arisen, and to consider to what degree the criticisms directly against the use of margarin and allied products are justified.

The product of the margarin industry, I understand, is confronted with competition, that of butter. The butter maker claims that his product is superior to margarin on account of the nature of the primary product being less refined and containing certain elements of nutrition to be referred to later. The development of our knowledge of vitamins has had one undesirable effect. It has enabled a certain school of nutrition to emphasize the value of natural foods which has found, of course, willing followers among food producers who are more than willing to exploit these ideas to their best advantage. The producers of natural foods avail themselves of class legislation which would permanently cripple and even annihilate the industry of artificially compounded foodstuffs.

The idea that we cannot improve food as provided for us by Nature is entirely wrong and reminds one of the idea, rampant in the first part of the nineteenth century, that the laboratory would never be able to dupli-

*Increasing knowledge of our nutritional wants has demanded the collection of specific data on food products of all kinds, with the result that no food, either natural or compounded, in the absence of laboratory tests can safely be assumed to meet physiological requirements.*

*The exploitation of the vitamin doctrine may at least be credited with placing upon food manufacturers and distributors the onus of proving the existence of constituents claimed. It has thus become possible so to manufacture margarin as to certify anti-rachitic and anti-ophthalmic properties as well as to insure a constant vitamin content.*

cate organic products as elaborated by Nature in the plant and animal cells. The word "never" does not exist in science. As early as 1827 Wöhler synthesized urea, the first natural product made artificially in the laboratory. Since then, hundreds of such products have sprung from this fecund source and have proved identical in every respect with the products elaborated by the cell.

### Margarin as a Fat-Component

The same situation applies to our fats. With increasing knowledge of our nutritive wants, and data being collected with marvelous speed, there is no reason why we cannot compound food mixtures superior in nutritive value to the products provided for us by Nature. You see a very similar situation in the skimmed milk industry. Its products were fought by the milk-producers on very much the same ground as the butter producers fought margarin, namely, the deficiency of vitamin A. After much effort was spent by the adversaries of the skimmed milk compounds, a product appeared on the market which contained a certain proportion of cod liver oil. This product has been tested successfully on a number of infants and can be made

richer in vitamin A than original milk. Inasmuch as legislation could not debar such a product on the ground of deficiency in vitamin A, the adversaries of skimmed milk products will be compelled to find other reasons for its prohibition. If I am not wrong, all the skimmed milk compounds will be modified in the future in some similar way. This, it seems to me, indicates clearly a future tendency of the margarin industry. Unfortunately in the margarin field direct-feeding experiments are scant, and those bearing upon the vitamin content practically absent. This is why I shall have to limit myself to somewhat indirect conclusions, based on analogous experimental work.

Whatever may be the source of margarin, its utilization in the body, that is its caloric value is equal to that of butter in the physiology of nutrition. We have been unable to detect any difference between the various fats in this respect with margarin. Whether the raw materials of margarin are of plant or animal origin, we are not dealing with fats foreign to the body, as the same fats are a part of our regular diet. Their fate in the body is the same. They are partly split by the pancreatic ferment, steapsin, into their components, glycerol, and fatty acids are resorbed by the intestinal wall in the form of soaps, which form largely the triglycerides which can be used or stored up by the body.

The chemical nature of the various fatty acids derived from margarins or butter gives us no reason to believe in any real difference as to their utilization by the body. As a matter of fact, all the edible fats, including margarin, have the same coefficient of digestibility, from 97 to 98 per cent, and yield on combustion the same amount of calories. One of the latest textbooks on dietetics\* (v. Noorden and Salomon) says that margarin when prepared in the proper way and from sound ingredients can be used in place of butter. We see from the few words above that nobody can claim any nutritional difference between margarin and butter,

\*Read before the third annual convention of the Institute of Margarin Manufacturers, Detroit, Mich., May 22-28, 1922.

from the point of view of its fat nature alone. All criticisms directed against margarin as a food originated from the results of vitamine research. It is this aspect of the problem that I here wish to emphasize. The new developments of vitamine research are too well known to be dwelt upon here. I shall restrict myself to the vitamine associated with fats, vitamine A, and which has a direct connection with the production and distribution problem of the margarin manufacturers.

Knowledge of vitamine A has many new and recent developments. Shortly after I had assumed theoretically the existence of a specific antirachitic vitamine in cod liver oil, McCollum, with his collaborators, and simultaneously Osborne and Mendel demonstrated the existence of a vitamine associated with fats which plays an important rôle in the nutrition of certain animals and presumably also of man. I say here expressly "certain animals," as recently I have been able to keep adult pigeons for 140 days on a diet free from this vitamine. First it was assumed that vitamine A was associated only with animal fats, particularly butter, egg yolk, and cod liver oil, but lately its presence has been demonstrated in a number of plant products, especially green vegetables and also some seeds and roots. Vitamine A has been found to be much more widely distributed than was at first surmised. So much so, that in our experimental work we must take great care to free the diets from this admixture. This is done usually by a combination of extraction with fat solvents and submission to the action of air (oxidation) at high temperature.

Even with these precautions the reports from the various laboratories are far from consistent. Some experimenters (Drummond and collaborators) report that on carefully purified diets young rats stopped growing after ten days, whereas Miss Patton and myself are unable to arrest growth completely even after two months and longer. It seems not impossible that besides the variations in the laboratory conditions, various breeds of rats show differences in their vitamine A requirements. As regards the absolute requirements of a rat for vitamine A, we are not informed. It is assumed, however, that 5 per cent of butter in a diet is sufficient, and as a rat of 50 to 60 gram's weight consumes about 5 to 6 grams of a standard synthetic diet, this means an equivalent of 0.25 to 0.30 grams of butter a day.

Similarly, according to Zilva and Miura, the requirements of a rat in terms of cod liver oil vary between 0.0017 to 0.005 grams per day. This means that cod liver oil on an average is one hundred times as potent as butter. For a two-year old child (11 kilograms) this would mean 46 grams a day in terms of butter and 0.36 grams in terms of cod liver oil. Judging from the amount of butter or cream in its diet, a child of two years gets not far from this amount. With rats, the vitamine requirements as regards vitamine A have been found to be materially smaller when the rats approach maturity. From analogy we must surmise that the same facts apply to adult man.

We are entirely in the dark as to what rôle vitamine A plays in the animal economy. We know that in its absence certain young animals at least cease to grow, but a lack of any essential constituent of food causes a similar result. We know that resistance to infections, particularly of the respiratory organs, is diminished but this might not be specific for vitamine A. We know only of one apparently specific connection and that is the occurrence of ophthalmia (xer-ophthalmia) following vitamine A deficiency; this is an eye infection which I will describe a little more in detail.

#### Ophthalmia Due to Diet

This condition has been described in a number of laboratory animals and also in children, when placed on a diet deficient in vitamine A. First regarded as a deficiency disease, in the same sense as beriberi and scurvy, it doubtless ultimately will prove to be an unspecific infection of the eyelids and cornea, a sequence of deficiency in vitamine A. What the real connection is between these two phenomena is still unknown; it seems to us that the etiology of ophthalmia requires a good deal of further study, as was emphasized by Walker<sup>1</sup> not long ago. Indeed, no pathological changes have so far been detected to justify this sudden invasion of bacteria.

As regards the time necessary for the development of ophthalmia, the available data vary a good deal, most of the investigators reporting the necessary time to be six to eleven weeks for rats and for dogs almost one hundred days. This means that a long continued deficient dietary must be instituted before symptoms manifest themselves. As regards the percent-

age of the animals so affected, there also is a considerable discrepancy in the available data. While Osborne and Mendel, who have the largest amount of statistical material on rats at their disposal, report fifty per cent of the animals affected by ophthalmia, Emmett reported almost one hundred per cent. It seems to me that cleanliness has something to do with the incidence; when a number of rats are kept together in one cage the incidence seems to be greater than when they are kept separately and cleaner. It is often disappointing when one desires to produce ophthalmia for the purpose of testing fractions obtained from cod liver oil, to see the small percentage of animals which finally develop it and also the length of time necessary for this purpose. To summarize our personal experience on the subject, we find that the only definite manifestation of a deficiency in vitamine A, ophthalmia, needs further studies under uniform conditions as regards sanitation, age and breed of animals, and the method of food preparation.

Through the progress made in the last few years in the study of rickets, the problem of vitamine A presents a somewhat changed aspect, especially in connection with the subject of margarin. In accord with my conception that vitamine A has antirachitic properties, and with Mellanby's experimental work on young dogs, milk should be regarded as a food which is able to protect a young animal or a baby from rickets.

However valuable this would be from the standpoint of milk and butter being "the perfect food," modern investigations on rickets have demonstrated clearly that, strange as it seems, milk and butter both are unable to protect a young animal from rickets, while cod liver oil possesses these properties to a very marked degree. At the same time, as we already have seen, cod liver oil contains much more of the substance which is curative for ophthalmia than does butter. Should this phenomena be interpreted to mean that for curing ophthalmia and for resumption of good nutrition and growth, small quantities of vitamine A suffice, while for prevention of rickets large quantities of the same substance are necessary? Or should it be explained by the existence of a separate antiophthalmic and antirachitic vitamins, as McCollum and his collaborators recently suggested? These questions will be clearly answered only when the two fractions from cod liver oil are separated from

\*v. Noorden and Salomon: Springer, Berlin, 1920.

1. Walker, S., Jr.: Jour. A. M. A., 1922, lxxviii, 273.

each other in a chemical way and tested for both actions. Whatever the final outcome of this issue will be, it is important to know that milk fails us in its antirachitic properties, and that we had to hunt for protection by using cod liver oil and other factors, which, however, is not within the scope of our present consideration.

### Chemistry of Vitamine A

While the elucidation of the chemical nature of this vitamine, particularly its antirachitic variety, has seemed hitherto very remote, the recent progress made in the methods of testing makes justifiable the hope that the antirachitic vitamine will not remain to us a complete mystery very much longer. It seems to me that the leading food industries can not afford very much longer to relegate vitamine A to a class of mysteries, always to remain as such in the future.

First, in the method described by McCollum, Simmonds, Shipley and Park<sup>2</sup>, we possess means to test for the presence of the antirachitic vitamine. The test is made on rats on a diet containing a low proportion of phosphorus and vitamine A and a high proportion of calcium. After thirty to thirty-five days the fraction to be tested is given to the rats daily for five days. After this time the animals are killed and their bones examined for fresh deposition of calcium salts. The test in our hands proved to be entirely reliable. Having this test at our disposal, material advances have been made in the chemistry of the antirachitic vitamine.

The chemistry of antirachitic vitamine was started by the author in 1912 when no physiological methods were available for testing for the presence of this substance. In 1914 McCollum and Davis<sup>3</sup> saponified butter and extracted the vitamine A with olive oil. This hopeful method was not exploited by the above investigators. While Drummond<sup>4</sup> failed to achieve success by using the saponification method, Steenbock and his collaborators<sup>5</sup> made a very important advance in the same direction. Cod liver oil was found quite stable to saponification with 20 per cent alcoholic potash solution, boiling the mixture for four hours; and what is still more interesting for us, the active substance could be extracted from the

soap solution with ether and concentrated in this way.

A more recent paper by Zucker, Pappenheimer and Barnett<sup>6</sup> signifies a further very desirable step in the same direction. Here the fatty acids and cholesterol were separated from the saponified oil and found inactive, while the mother liquor was more active than before. In this way the final fraction could be made as concentrated as desired.

By an entirely different procedure, which will be described in detail in collaboration with Dubin in the near future, we have obtained the antirachitic vitamine a hundred times more concentrated as compared with the original starting material. Besides the scientific interest and the well founded hope to get at the chemical nature of this vitamine in the near future, the practical application of this very substantial advance is obvious to all of you. It remains to be investigated how long these concentrated preparations will remain active but if they do, the problem of making food products deficient in vitamine A richer in this substance, is practically solved.

It is regrettable that we possess hardly any scientific data on this, at least theoretically, if not practically, important subject. Besides the fact, shown by Osborne and Mendel<sup>7</sup> that the oleo portion of the beef fat contains all the vitamine A, while the solid portion is deficient in it, and the investigation of Halliburton and Drummond<sup>8</sup> who made a more thorough investigation, not many data are available. Unfortunately these latter workers, while stating the source of the products, did not mention at all the way they were manufactured. Their results were as follows: Margarins of animal origin were found to contain vitamine A. Margarin of plant origin did not permit normal growth but prevented ophthalmia. Nut butters and lard substitutes made from hydrogenated vegetable oils also were found to be deficient.

It must be borne in mind that these results are based upon English margarin which under the existing law may contain as high as 10 per cent of butter, and might, therefore, give better results due to the presence of this admixture.

It is self-evident that in each margarin factory the vitamine A content of the finished product will vary and has to be determined specially in each

case. The vitamine content of the finished product will depend on the vitamine content of the raw materials, the amount of milk constituents in it and the method of manufacture. For instance, it has been shown repeatedly that the aëration of the food, especially in conjunction with heating, is detrimental to vitamine A. This has been shown for lard by Drummond, Golding, Zilva and Coward<sup>9</sup>, that the method of rendering the lard is of significance for the vitamine A content of the finished product. This also is in accordance with the statement of Daniels and Loughlin<sup>10</sup> who have found that some samples of lard contained a noticeable amount of this vitamine. Heating and simultaneous oxidation is the method used in the laboratories for rendering the ingredients of the basal diet free from vitamine A.

### Dietetic Aspects of Margarin

All that I have said here can be applied in the practical procedure of margarin manufacture. It is quite probable that most of the natural foods contain some vitamine A which could be preserved by taking proper precautions. While hydrogenated fats are regarded at present as vitamine-free, the present method of hydrogenation involves high temperatures, and it should be worth while to investigate whether or not a cheap method of hydrogenating oils could be devised which proceeds at low temperature and which would be not so destructive to the vitamine. In margarin manufacture a mixture could be selected to include a food ingredient with a naturally higher vitamine content of the type of oleo. Finally, by eliminating the destructive factors, the original vitamine content could be more efficiently preserved.

In considering the nutritive value of margarin, we naturally have to compare it with butter. Since the discovery that fresh milk, cream, and even butter display only an insignificant antirachitic potency, the dietetic position of margarin has been strengthened materially, since in this respect no noticeable difference has been established. On the other hand, the necessity of laws in all countries regulating the total solids and fat content of milk, shows conclusively that not all milk producers are concerned particularly with the health of our babies. In this respect we are

11. Kennedy and Dutcher: *J. Biol. Chem.*, 1922, l, 339.

protected fully, but a new problem has come up which requires in our opinion new legislation. This is the logical postulate first suggested by us and now experimentally fully confirmed. We are speaking here of the dependence of the vitamine content of milk on the vitamine content of the feed of the cow. At the present time probably most of the winter milks are decidedly lower in vitamine value as compared with summer milks; we can conceive, theoretically at least, the possibility of milk and butter being almost entirely vitamine free. As Kennedy and Dutcher<sup>11</sup> have lately demonstrated, the winter milks by a suitable choice of feed could be rendered as nutritious as summer milks and on such selection we should insist. The vitamine content of the marketed milk should be tested by the authorities and rapid methods for such tests should be devised.

The margarins are not a substitute for milk but a substitute for butter and as such have fulfilled well the requirements, except for deficiency in vitamine A, which as yet is not accurately determined. This vitamine, according to our present knowledge obtained from experiments on rats, is required more by the young, growing animal, than later in life. Judging from the occurrence of ophthalmia in children, when their diet is limited to highly skimmed milk as a source of vitamine, the human requirements for vitamine A seem to be analogous to those found for rats.

The paucity of ophthalmia cases in central Europe during the war shows us that even in times of serious deficiency of fats the human organism, especially adults on mixed diet, can quite easily limit this deficiency. In children still on a one-sided diet, replacing butter by margarin of the present type may not always be desirable unless the diet is supplemented by a product rich in vitamine A, like fresh green vegetables, eggs, or cod liver oil. With adults, on the contrary, for whom the requirement of vitamine content are smaller, the use of margarin has no dangers of deficiency. Any of the existing textbooks on vitamins give a long list of foodstuffs which enter into everybody's dietary and which more than offset the partial deficiency of margarin. For cooking purposes, while no actual experiments are available on this point, it seems to us that margarin safely could replace butter. In frying and cooking it is likely that the vitamine A of butter is for the most part destroyed by oxidation and may possess no advantage over margarin.

The margarins, as we already have seen, are fully equal in nutritive value as regard their content in fats and the number of calories they yield, to butter and nut butters. From the standpoint of our present knowledge of nutrition, you can safely proceed as you have done successfully in the past, but if you wish you could disarm entirely your opponents. Margarin differs dietetically from butter only in its diminished content of vitamine A. This seems to us the only scientific ground on which legislation adverse to the development of margarin manufacture could be attempted. In spite of the fact that such legislation for reasons already explained, does not find justification in our eyes, this problem seems sufficiently important to the trade association of margarin manufacturers to invite a vitamine expert to address its convention. If I am right in this assumption, nothing seems easier to me than to restore or supplement the deficient vitamine. As I have stated above, a better selection of raw materials and avoiding injury of the sensitive vitamine A will remove partially this difficulty. How far this is possible with your present processes of manufacture, I cannot state. To go a step further, you can make your margarin as rich or richer in vitamine A than butter is. I have here in mind the addition of a small amount of cod liver oil. The product thus improved would have a distinct advantage over butter in that it would be antirachitic as well as antiophthalmic; and, in variance with butter, it would have a constant vitamine content.

A certain amount of experimentation on this subject appears to be necessary, but judging from the requirements of rats for butter as compared with cod liver oil, 0.36 gram of the latter is equivalent in value to 46 grams of butter. This means that to a pound of margarin three to four grams of cod liver oil would have to be added or .04 grams of the concentrated vitamine fraction which has been obtained from the oil. This latter addition would constitute only one hundredth of 1 per cent of finished margarin. It is tasteless and odorless.

Millions of pounds of margarin sold yearly to the public perhaps may not show the manufacturers the desirability of any further improvements in manufacturing processes, but to my mind, the exploitation of the vitamine doctrine by competitors renders a new step in the development of the margarin industry very timely and most wise.

## Defective Drains and the Spread of Infections

The advance in sanitation should claim the major credit for the decrease in incidence and in virulence of scarlet fever in recent years, according to Dr. J. Allan Gray, of Edinburgh, in a recent communication to *The Lancet*. Those with first hand experience of scarlatina in hospital and private practice have for many years been agreed that the possibility of transmission through desquamation is an almost negligible quantity, but that the risk from contamination by the discharges from mouth, nose, and ears is real. Prevent these discharges from reaching the uninfected, and no spread occurs. This may be quite easily and safely done in private, given a trustworthy attendant and suitable housing.

As an illustration of what may be done under duress of circumstances, Dr. Gray relates that in old days, when hospital accommodation was limited, he again and again treated without spread, a case of scarlatina in a two room house in a tenement, the patient occupying one room with the attendant (separate beds,) the father and the rest of the family occupying the other room, the attendant cooking, etc., for all. All infected spoons, cups, etc., were placed in boiling water immediately after use, rags used as handkerchiefs burned, and the admonition repeated at each visit that, as scarlet fever enters the uninfected largely through the mouth, it was incumbent upon the attendant to prevent this from happening to other members of the household.

The fact that cases of scarlatina are not as severe as in the old days and the mortality less, Dr. Gray attributes to the advance in sanitation since in the past the worst cases, whether in slum or suburb, were associated with defective drains. While it may well be that the virus of the disease has become attenuated in its passage through a population whose successive generations have been subjected to the infection, it is all to the good that the said population possesses the advantage of concurrent improved sanitation.

Dr. H. Cilento of the Australian Department of Health has come to America to study the methods used by the late General Gorgas in making Panama hygienic and sanitary. After two months he will go to New Guinea to take charge of the medical and hygienic administration of the island now under Australian control.

# The Social Hygiene Campaign in Florida

## Lectures, Films, and Clinics Are Weapons in Fight for Eradication

By WILLIAM BIERMAN, A.B., M.D., NEW YORK CITY

THAT venereal diseases are preventable in theory is agreed to by all. Their etiology is well known and their method of transmission is definitely established. That these diseases are preventable in actuality is still doubted by many. These are willing to concede as a true fact that the number of cases in the army would have been much higher were it not for the institution of measures which composed the so-called American Plan. They doubt, however, as to whether this same plan of action will be effective among a peace-time population. Obviously, there are only two lines of conduct which can be followed in a consideration of this sort. Either to do nothing, or else to do something.

The great prevalence of these diseases and the enormous amount of human damage and death for which they are responsible precludes the possibility of our ignoring them. They must be considered because they form the scourge which is making the strongest threat against our existence. That this not a purely theoretical consideration is borne out by the impressions one gains in going through many sections of the South. In these places it appears as if the colored population is even now beginning to be threatened with extinction—due, mainly, to the common prevalence of sterility, for which the gonococcus is the chief responsible factor, and the mortality occasioned by the inroads of the *spirochaeta pallida*.

### Whole State Canvassed

During the draft examinations Florida had the unenviable distinction of leading the other states of the Union with regard to the incidence of venereal diseases among her citizens with a percentage of 15.63. The State Board of Health, therefore, determined to place the State in the van of those who are exerting every effort to diminish the incidence of these diseases and eventually eradicate them. With the cooperation of the U. S. Public Health Service, the American Social Hygiene Association, and the Interdepartmental Social Hygiene Board, an anti-venereal disease cam-

paign was launched.

For the purposes of this campaign, the state of Florida was divided into two sections,—the northern section, which is also the more western section, extending from Jacksonville to Pensacola, the remainder of the State forming the other portion. The western section of the State was covered by means of the automobile truck loaned to the state by the American Social Hygiene Association for a period of three months. This truck program had previously been carried out in North Carolina where it had demonstrated its great value.

This automobile carried all of the equipment necessary to show motion pictures at any places, any time of the day. It contained a Delco electric light generator; and storage batteries; a portable Powers projecting machine; screen; curtains for darkening buildings; and cables. Through its use we were able to convert schools, churches, and other public buildings into places where the motion pictures stood out clearly, even during daylight. Some sixty communities lying between Jacksonville and Pensacola were visited during these three months. Showings were made before audiences of women in the afternoon at 3:30 and for the men at night at 7:30.

For the women the so-called women's lecture film was used. The men were shown the men's lecture film. The exhibition of both films was accompanied by a lecture, the general purpose of which was to explain the pictures thrown on the screen, in accord with the varying intelligences of the audiences as judged by the lecturer; to emphasize the seriousness of these diseases; and to indicate ways in which they might be prevented. The remarks made before, during, and after the exhibition of the pictures emphasized, too, the necessity of treatment at the hands of a physician and the inefficacy of self-medication; the fact that the diseases are usually acquired through illicit sexual intercourse—although they might be acquired innocently,—as for example through kissing; the necessity for telling the growing child the real story of how life begins that

the cast of his character might be molded along sexually moral lines at the time when those impressions could be most firmly fixed into his moral fibre.

The advent of the truck was prepared for in every place by the activities of the advance agent. He would arrange for the building where the pictures were to be shown; place placards indicating the date and place where the exhibition would be held, in the most prominent places in town; and cause letters to be distributed to all the holders of boxes in the post-office, giving the same information. As a result of these activities, a very large proportion of the inhabitants invited, those over 14 years of age, would appear to witness the exhibitions. These were well received. Many were the words of gratefulness expressed after the showings for the information given concerning these vital questions.

The Southern portion of the state was covered by what was called the "towns and cities" campaign. Some thirty of the larger communities were chosen for the activities of this campaign. In these places the leading citizens, those most influential and most appreciative of the need for combating venereal diseases, were gathered together and were asked to appoint of their number some small group to act as a permanent committee to keep up the fight against venereal diseases. The leading women were similarly organized.

### Local Committees Organized

We recognized that though a single exhibition of motion pictures and lectures was of great value, it was necessary to maintain continued effort along these lines for many years before our eventual objective, the eradication of gonorrhoea and syphilis, could be reached. For this purpose committees were organized to act as local representatives of the agencies, Federal, State, and private, who are interested in this fight. It was felt that the townspeople who composed them would be more conversant with local conditions and, therefore, in a better position to apply the various phases of the "American Plan."—recrea-

tional educational, medical and legal,—to their respective communities.

The State Board of Health has acquired motion pictures, a great mass of educational literature, and placards for exhibits, which it stands ready to furnish these committees in furthering their efforts. In addition, it was felt that these representative groups could also, if they so chose, draw upon the venereal division of the U. S. Public Health Service and the American Social Hygiene Association for advice, material and other aids they might desire in pushing the anti-venereal disease campaign in their towns.

The enthusiastic response made by the citizens of these towns in the inauguration of these committees augers well for the successful continuation of the work, the foundation for which was laid during this campaign. The legal phase of the campaign consisted in the presentation for passage by the state legislature of laws aimed against prostitution.

As the result of an invitation extended to me by means of a resolution passed in the Florida State House of Representatives, I and the other workers in this campaign had the opportunity of showing our motion pictures to the legislators and explaining the purposes of our undertaking.

The medical phase of the campaign aimed to improve the treatment ac-

corded patients suffering from these diseases. In order to provide for the indigent, gonorrhoeic and syphilitic clinics have been established at most of the county seats throughout the state.

How to take care of these indigent patients at a minimum expense to the state was a problem. With the exception of the larger cities of Jacksonville, Tampa, and Pensacola, the so-called clinics have been established in the private offices of the doctors designated to take care of these cases. These doctors are furnished with the necessary medication—arsphenamine, mercury, and argyrol, with the armamentarium necessary for their proper application. To maintain these clinics the State Board of Health pays a small salary and the city and county are each asked to pay sums equal to the compensation given by the state. To reach the smaller towns an ambulatory clinic was established.

The results of all these activities cannot be judged until several years have elapsed. Those of us who have paid particular attention to this work feel that these measures are the most effective we have and that properly applied, as the result of continuous effort over a period of many years, we will finally reach that consummation we so earnestly hope for,—the eradication of venereal diseases.

## The Hazards of Old Age

IF THE psychologists desire indubitable proof of the universal tendency of the human mind to "side-step" reality and turn away from the rational consideration of what seems to it unpleasant, no better instance could be cited than the lack of attention, both individual and collective, which has been accorded to the problems of old age. Society assumes no collective responsibility for the aged and consigns to the scrap heap everyone alike whether the productive period has run its full course and entitles the aged worker to surcease of labor, whether sickness or other unpreventable conditions have unduly shortened the working period, or whether ruthless commercialism has caused industrial superannuation early in life. In fact, so meager, so painfully inadequate is public provision for aged dependents that Epstein<sup>1</sup> declares that "though the expectation of life has improved, it cannot be considered a blessing by the aged poor." The

almshouse is the final apotheosis of friendlessness and Epstein considers that of the greater army of the aged who are presumably non-dependent merely because they are not the recipients of charity, a sufficient number are below the poverty line to call for a far reaching and constructive social policy. The obligation of caring for the aged becomes a more concrete question in smaller groups and has been faced directly by the severally inadequate means of (1) individual savings; (2) pensions—individual, industrial and government; (3) retirement funds; (4) trade union superannuation benefits; and (5) insurance, both voluntary and subsidized. Epstein makes a comprehensive analysis of old age compensation systems of Europe and traces the development of the insurance idea in the United States. He stands committed to some form of social insurance for the relief of the aged.

1. Epstein, Abraham: *Facing Old Age*, Alfred Knopf, New York, 1922.

It is an interesting fact that even where pensions are provided only negligible numbers are reached. Of the industrial systems examined by a special committee of the Merchants Association, New York, the proportion of the total amounts spent in pensions to the total pay roll was rarely found to exceed 1 per cent. "Under the present condition of costs of living and wages, thrift and individual savings sufficient for old age cannot be seriously considered possible for many wage earners. Neither can the industrial systems be depended upon to take care of their aged workers, since they have no sure permanency and take care of only a fraction of the workers they employ. While the recent Federal Retirement plan will take care of many a needy employee, there still remain thousands of federal employees, as well as employees of state and municipalities who need to be protected. The fraternal and trade union old age benefit funds are generally insecure and at best the number that they can protect is inconsiderable." The individuals themselves are no more prone to anticipate the disabilities of age, for in Pennsylvania, in which state there are multifarious forms of industrial, municipal and fraternal pensions, only thirty out of every thousand persons sixty-five years of age and over are protected.

G. Stanley Hall<sup>2</sup> in his comprehensive book on "Senescence" speaks with the authority of a psychologist on the characteristic indifference of the multitude to the hazards of age. The early twenties can hardly be considered the most crucial period of life as the ages between forty-five and sixty-five witness by far the greatest wreckage of human material. Psychology offers no help to the aged man, for there are no mental tests of recognized validity above the teens to indicate whether a man is growing old normally or wisely, and psychoanalysts on the express authority of Freud refuse to take a patient over forty. Medicine is far from having developed any system of coherent gerontology, and, largely owing to the neglect of its problems, old age is now too commonly a hateful and even a ghastly thing. Hall, however, holds that the ideal of a greater old age is not an idle dream. There is no short cut to longevity; its achievement must be the work of a lifetime and many of the most serious drawbacks in later life are open to practical and simple

2. Hall, G. Stanley: *Senescence, The Last Half of Life*, D. Appleton & Co., New York, 1922.

remedy. It is not that the fear of death casts its shadow in later life. The aged suffer mainly from isolation, from a false old age imposed on the current belief that the age limit is "three score years and ten," and that usefulness terminates earlier than that. For we live in a society which has relegated to a false old age the relatively fit, and the aging population suffers from maladjustment, from isolation and enforced idleness,

and the difficulties of finding new uses for powers scrapped before they found expression. Hall states that the time is ripe for the formation of a society of senescents, national in scope, to relieve the isolation of the aged and to extend their period of productivity.

Medicine, too, must study the needs of age. We are freer from germs but our vital organs wear out sooner because of unintelligent use and lack

of conservative care. Old age is a risk to which all are liable. Self-respect and thrift require us to give more attention to it. After all, health care of the aged is an integral part of the program to prevent the premature death of everyone. It is an economic question only in part. It is more a medical issue. It is not a question of charity. If it is to solve the problem of the aged, charity needs to become a science.

## California Plans to Train Dental Assistants

By DOROTHY LOUISE MACKAY, M.A., SAN FRANCISCO, CAL.

IF the leading dentists and educators of California are successful in carrying out their plans, several California high schools will soon include in their curricula courses preparing girls for the occupation of dental assistant. At a conference held in San Francisco in the Autumn of 1920, the representatives of the State Board of Education and of the State Dental Association considered the possibilities of such a course and approved it as valuable and practical. Through cooperation with the Division of Vocational Education of the University of California, the services of a research worker were made available. She was to study the situation and to gather information which would enable her to make recommendations for a course of study.

The Dean of the College of Dentistry of the University of California sent out a letter to fifty leading dentists of San Francisco and the Bay Region who he thought might be interested. The letter stated that the State Board of Education and the State Dental Association were cooperating in an effort to establish a course of training for dental assistants, and outlined the plan of procedure. The research worker was to request of these dentists an appointment, to visit their offices, watch their assistant at work, and consult with them as to the needs of the work and of the course of training. A list of topics for discussion was enclosed in order that the dentist might think about the matter before discussing it with the research worker when she called. Some of the points on which their opinion was asked were: the age for entering the work, desirable physical characteristics — height, weight, health, etc.—types of personality, education, general suggestions for a course of training.

A second series of questions aimed

at an analysis of present conditions in the vocation,—hours of service, salary, experience necessary for efficiency, average length of service, and length of service with present employer. The letter included a request that those addressed assist the research worker in every possible way to obtain results.

### Survey Dentists' Attitude

The visits to the offices of the various dentists were characterized by great differences as to length of stay, opportunity for observation and discussion, attitude of the dentist, and results obtained. The first visit consumed practically a whole day. The office was that of a dentist who was vitally interested in the project, and who had been one of the original committee to formulate the plan. He introduced her to the mysteries of a dental office and laboratory, pointing out the more important equipment, instruments, and laboratory material. He assisted her in planning her visits to obtain the most satisfactory results. She next visited one or more offices of the several types including those of:

A.—Dentists with a general practice.

B.—Dentists whose practice was limited to special fields: (1) Extraction (a) local anesthesia, (b) general anesthesia; (2) surgery; (3) orthodontia; (4) diseases of the gums; and (5) mouth reconstruction.

C.—Dentists whose practice includes one or more of the above fields, but who share a suite of offices with other specialists in different fields.

After this tour of visits she went to the other offices on her list for the purpose of checking her notes. In this manner she covered nearly all of those on her lists, the visits lasting from an hour or less to a half-day or two half days.

The great majority of the men visited were greatly interested and anxious to cooperate. They gave freely of their valuable time to explain, demonstrate, discuss, and suggest. In only a very few cases was there any opposition or disinclination to assist. One or two said they had no time for an interview and could not permit a visitor in their operating rooms. One man said that nobody except a dentist was qualified to study the occupation, and resented "outside intrusion."

Two advanced the wornout argument used at some time or other concerning every occupation that has ever been analyzed for educational purposes: "You cannot prepare people for this job in any school or training course. The work varies too greatly to be standardized for teaching. Give me an inexperienced girl and I will train her to suit my individual needs. Experience with another employer is a handicap rather than an asset."

The overwhelming majority were of the opinion that a course for dental assistants was not only a project of possible value but indeed a necessity. Many reasons were advanced in its favor.

At present the dentist is compelled to select his assistants from among a promiscuous group of applicants. He rarely finds one who has any definite experience which will be of value to him. He is usually more successful with an inexperienced girl than with one who has been trained by another dentist, for such training has frequently been individualistic and one-sided in character. She lacks a broad vision of her work.

The services of such an assistant, at least until after she has been with him several years, are not worth a liberal compensation. The dentist cannot afford to pay a high salary

until the worker earns it. It is difficult to get desirable material at the salary paid.

The turnover is very high. Many girls take up this work as a make-shift until they can obtain some object they desire. This may be marriage or some goal in the educational or industrial field. Some are waiting for an opportunity to enter a training school for nurses. Others are studying commercial subjects with a view to entering the business world. However worthy the object, the fact remains that many who are entering the occupation of dental assistant have no intention of remaining in the field. This does not tend toward a high standard for the occupation.

The girl now entering the occupation is an untrained worker, and as such must cope with certain disadvantages. In the first place, she cannot expect a good salary, even though she may have had years of experience in the field, for to a new employer she is worth little more than a beginner.

Secondly, she must learn on the job. She has no background which will enable her better to understand her work. Any scientific training she may have had was in such a form as to bear little or no relation to the problem confronting her. She must pick up her training by following whatever directions it may be found necessary to give her. The employer has no time to devote to giving her a graduated, progressive system of training which would fit her to fill any position. He must show her how to do the things he needs done, whenever he happens to need them. Not only does she learn exclusively the processes necessary to the particular kind of work her employer does, but she learns how to do these jobs in one particular way. Other methods might be far more efficient. In fact, if she understood the whole problem more thoroughly, she might be able to work out ways and means which would prove more successful, and would save time. However, such an opportunity rarely comes except with years of experience.

Then, too, if for some reason, possibly through no fault of her own, her employment with one person is terminated, she is compelled to seek another position at a beginner's salary, and to learn her job all over again.

Lack of training has been in many cases responsible for the inability of the assistant to meet the public. Some persons resent the attitude of employees who do not understand this part of their business. This leads to

friction and misunderstanding frequently resulting in loss to both dentist and patient. Likewise inability properly to manage the office routine and bookkeeping causes inconvenience to patients as well as to the dentist. This does not imply that all workers in the occupation are at present inefficient and incompetent. There are a few dental assistants who have proved themselves qualified for their positions to a remarkable degree. Most of these have very unusual personalities and have worked for years with one employer. They are the persons who would have most profited by training.

There are few positions in which tact and efficiency are more necessary, and these can be developed properly for this type of work only by definite instruction. It was the consensus of opinion of those visited that a properly organized course could remedy many, if not all of the defects of the present system.

#### Benefits of Such a Course

It would provide definite training for an occupation which has proved desirable to a large group of workers. Upon completion of the course the girl would be fitted properly to fill a position, to understand her work, and to expect a salary commensurate with her value. In a course of training attention could be given to all phases of the work, thus centering the instruction around the needs of the worker rather than about those of an individual employer. A worker need no longer begin over again when her service with one employer is terminated.

It would provide for the dentists a group of trained assistants whom they could expect to be adequately prepared and fitted to do the work required. The only additional training needed by them would be instruction in a few details peculiar to his individual practice. He could accomplish a great deal more in a given time, for his assistant could anticipate his needs and take from him the responsibility of the details which ordinarily trouble him. This would be a financial gain as well as a physical and mental relief.

It would open up a new field for trained workers and raise the standard of the occupation. The public would no longer be caused the inconvenience of dealing with inefficient and tactless individuals. A digest of the findings resulting from these visits was compiled in the following form:

#### I.—General Facts Concerning the Job.

Place of employment: Office and

operating room of a practicing dentist.

Length of the learning period: Two years.

Usual length of service: Comparatively short in most cases, due to lack of preparation.

Special health risks: None.

Age: .....16 or over.....

Sex: .....female .....

Special skill: ...manual dexterity..

Personal: .....pleasant, tactful, courteous, obedient, neat, calm, dependable, resourceful.

#### Physical:

Height .....medium or below...

Eyesight .....good .....

Strength .....at least normal....

Appearance ..immaculate, business-like, inconspicuous.

Education .....two years of high school including.

*English.*—Correct use of the written and spoken language. Elementary business correspondence. Writing letters for such purposes as requesting an interview, making or breaking an appointment, sending or requesting the payment of a bill, ordering supplies, asking or giving information. Spelling, with emphasis on the use and meaning of medical terms. The cultivation of a pleasant speaking voice.

*Mathematics.*—Review of elementary processes in arithmetic for speed and accuracy.

*General Science.*—Physiology and hygiene, chemistry of metals and solutions used in dentistry, physics, especially relating to electricity and dental apparatus.

*Commercial.*—Typing, elementary bookkeeping.

#### II.—Duties of Dental Assistant.

General office work.

Open office and put it in order.

Attend to heating and ventilation.

Keep desks, tables, and trays clean and in order.

After work on each patient, clean all surfaces exposed to contamination.

Answer telephone and door bell.

Make appointments and keep record of them.

Prepare daily card list of appointments.

From daily card, chart operations completed on each patient and time spent.

Keep office books.

Make out and send monthly bills and statements, receipts, etc.

Pay bills.

Bank money.

## Care of patients.

- Meet patient and take name.
- Call patient from waiting room.
- Take charge of his belongings, for example, glasses, wraps.
- Seat patient in chair.
- Adjust chair, headrest, towels.
- Assist patient when operation is finished.

## Assisting the dentist at the chair.

- Lay out instruments for given work.
- Pass instruments as needed.
- Remove instruments when no longer needed.
- Assist in operating by keeping patient's mouth in as favorable condition as possible, for example, by using compressed air bulb, or sponging blood.
- Assist in operating by holding saliva tube, ball-burnisher, mirror, or other instruments in place.
- Assist with rubber dam and absorbent rolls.
- Prepare local anesthetic, and fill syringes.
- Mix plastic fillings.
- Anneal gold.

## Care of instruments.

- Clean and sterilize instruments and supplies.
- Sort instruments and put them in place.
- Sharpen some instruments, such as chisels.
- Separate instruments not in good condition.
- Keep dentist informed as to number of instruments of each kind in good condition.

## Care of supplies.

- Keep record of supplies on hand and needed.
- Order medical supplies.
- Order cotton and gauze preparations, such as absorbent rolls, napkins, cotton absorbent points, dental floss.
- Make up emergency supplies.

## Occasional Duties

## Laboratory work.

- Pour models.
- Make base plates.
- Cast inlays.
- Make amalgam dies.
- Polish bridges.

## In anesthesia.

- Administer anesthetic or assist with patient under anesthesia by watching pulse, respiration, and eyes, or by using emergency measures in case of shock.

## In radiography.

- Take and develop pictures.
- Mount and keep plates.
- Keep radiograph records.

## III.—Knowledge Required in Terms of Teaching Units.

## Business practice.

- Typing.
- Keeping office records, books, appointments, accounts.
- Keeping card files: operation records, histories, examination records, x-ray plates and findings, etc.
- How to draw and bank money.
- Ordering office supplies: stationery, towels, soap, paper cups.

## General science, including:

- Physiology of the mouth, of the nervous system, and of the respiratory systems. Emergency measures in case of shock or hemorrhage. Effect of anesthesia, care of patient under anesthesia.

- Hygiene and sanitation. Principles of ventilation and heating. Principles of asepsis and sterilization.

- Health. Care of the body, especially feet, teeth, and nails. Posture and clothing.

## Equipment and instruments.

- Operating chair and its adjustment.
- Sterilizers and their operation.
- Sterilization without machines.
- Cleaning and sharpening of instruments.
- Names and use of instruments.
- Construction and use of bulbs and syringes.

- Technic of operations. Order of use of instruments.
- Adjustment of clamps and rubber dams.

- Detection of defects on instruments.
- How to hold and pass instruments.

## Dental supplies.

- Purposes and effects of medicines used by dentists. How to order them.
- How to order cotton and gauze supplies.
- Use of Dental rolls, absorbent points and pledgets, napkins, iodoform gauze strips, dental floss, etc.
- Sterilization of cotton and gauze supplies.

## Laboratory technic. Dental mechanics.

- Use of the Bunsen burner, alcohol lamp and annealing trays.
- Use of all appliances of dental laboratories.
- Preparation of plastic and gold fillings.
- Making base plates.
- Making and investing wax patterns.

## Making amalgam dies.

## Polishing bridges.

## Professional ethics and decorum.

- Moral standards and behavior.
- Attitude toward employer and work.

## Reception and dismissal of patients.

- Dealing with various types of patients, such as children, old people, hysterical persons, neurasthenics.

## Conversation.

## How to use the telephone.

## Appearance: clothes and hair.

## Electives for advanced students.

- Court for anesthetist: administration and control of general anesthesia.

- Radiography: How to take dental radiographs. Developing, filling.

## IV.—Promotional Opportunities.

The present system of selecting dental assistants promiscuously and of training them only to fill an individual job, limits promotion almost entirely to increase in salary. In some large offices where the dentist has an extensive general practice, and where several assistants are employed, there are promotions from one position in the office to another requiring greater skill, and entailing greater responsibility. This is likewise true where several dentists share a suite.

In a few isolated instances, dental assistants have advanced to special fields. Preliminary training will open up these fields more generally to promotion. Some of these are: Dental laboratory assistant; dental laboratory technician; executive positions in dental supply house; dental radiographer; and anesthetist.

Properly qualified dental assistants have occasionally taken courses at the College of Dentistry, and have become dentists. This course, together with the new course now being given by the University of California for dental hygienists, opens up opportunities for study and advancement for those who desire such.

A course of training for dental assistants would thus raise the standards of the vocation from that of the unskilled occupations to a high grade job requiring trained workers, and offering promotion possibilities. Is it not, therefore, worthwhile? California thinks so. One board of education is preparing to introduce the course into its technical high school at an early date. In fact, they are already offering a part of the course in an evening school for girls already employed as dental assistants.

A course of study is under preparation which will be sent out to boards desiring to introduce the course. It is planned to have the girls take the regular college preparatory course for two years, including those science courses which will form a foundation for some of the technical training. With the third year the vocational training will begin. She will still spend part of her time at academic work, but half the day will be devoted to the mechanical part of the course for dental assistant. During the fourth year she will spend half her day on academic subjects. During the first term she will devote her afternoons to those subjects of the

technical course included under "Knowledge required in terms of teaching units" which have not been covered in the laboratory work of the previous year. During the second term, her last in school, she will spend her afternoons in gaining practical experience in her occupation. She will be employed under salary by a dentist. She will either assist a recently licensed dentist, whose practice does not warrant his employment of an assistant for full time, or she will go to the office of some dentist who uses the services of more than one assistant. Here she would be assistant to, and under the supervision of the full time employee.

When she has completed her course, she will be a regular graduate of the high school, and accredited to the university. She will also be proficient in her chosen occupation, as she has had not only the theory, but the practice.

The faculty of the College of Dentistry of the University of California is now working out the details of the technical courses. They plan to outline all the work to be given, and to include diagrams and drawings of all equipment. They expect to have this so graphically represented that the course can easily be presented in a uniform manner in any community which may desire to introduce it.

## A Compilation of Current Notions on Feet

### Tabulated from Inquiry Made of One Hundred Orthopedists and Thirty-Five Non-Medical Men

By HERMAN W. MARSHALL, M.D., BOSTON, MASS.

**A** QUESTIONNAIRE on the basis of fifty items fundamental to the intelligent management of feet was prepared by the writer and distributed to orthopedists and retail shoe merchants. One hundred orthopedists from many cities of the United States and Canada have replied, and thirty-five non-medical answers have been received.

The original fifty statements with additions, comments and criticisms received are given in part below, and may be considered to represent the consensus of the opinion of medical and non-medical men on each item.

A few persons returned the set of questions without signatures. Others signed their names but made no criticisms. A few were liberal with comments. Many expressed their approval of the plan and the large majority of replies showed very considerable care in their preparation, so that only two were discarded as being unreliable. The entire set was examined personally by the writer, and very brief discussion of results is undertaken at the end of this paper. An asterisk has been used to identify the non-medical comments included in tabulations and may be considered to represent the consensus of the opinion.

#### QUESTIONNAIRE

(1)—*Shapes of feet and usefulness of feet vary independently.*

Orthopedists agreed, 99=99%; disagreed, 1=1%; doubtful, 0=0%; no opinion, 0=0%.  
Shoe dealers agreed, 35=100%; disagreed, 0=0%; doubtful, 0=0%; no opinion, 0=0%.  
Duluth, Minn.—Disagreed.

(2)—*Some misshapen feet are strong and*

*serviceable because muscles and ligaments that hold foot bones together and move them are unusually strong.*

Orthopedists agreed, 98=98%; disagreed, 0=0%; doubtful, 2=2%; no opinion, 0=0%.

Shoe dealers agreed, 34=97%; disagreed, 0=0%; doubtful, 1=3%; no opinion, 0=0%.

Boston, Mass.—The reason given why some misshapen feet are strong and serviceable is doubtful.

Boston, Mass.—Dr. A. G. Howard: Not the only reason.

(3)—*Some well formed feet are weak and unserviceable because muscles and ligaments are beginning to weaken from some cause, or because disease of bones or joints of the feet exists.*

Orthopedists agreed, 98=98%; disagreed, 0=0%; doubtful, 2=2%; no opinion, 0=0%.

Shoe dealers agreed, 35=100%; disagreed, 0=0%; doubtful, 0=0%; no opinion, 0=0%.

Pittsburgh, Pa.—Dr. E. W. Fiske: They will not remain well formed if weak.

Shreveport, La.—Dr. L. C. Spencer: Doubtful.

(4)—*Majority of feet are sufficiently well formed and serviceable to do the work required of them, yet there is a wide range between maximum and minimum degrees of usefulness exhibited by such feet among different persons.*

Orthopedists agreed, 98=98%; disagreed, 0=0%; doubtful, 2=2%; no opinion, 0=0%.

Shoe dealers agreed, 33=94%; disagreed, 2=6%; doubtful, 0=0%; no opinion, 0=0%.

Los Angeles, Cal.—Dr. C. L. Lowman: This seems to be too inclusive. Fifty per cent of all people have some faulty foot statics. Your use of the word "serviceable" would lead one to think that one cannot have symptoms due to feet unless there were symptoms in the feet. Many feet of the type I mention are perfectly serviceable as far as feet are concerned, but the use of them represents many times a very serious nerve loss because of faulty balance. In other words, many remote symptoms are traceable to feet that are apparently symptomless in themselves.

(5)—*Heights of arches do not measure the strength of usefulness of feet accurately. Numerous symptomless strong feet are observed, as well as weak contracted feet with unusually high arches.*

Orthopedists agreed, 100=100%; disagreed, 0=0%; doubtful, 0=0%; no opinion, 0=0%.

Shoe dealers agreed, 34=97%; disagreed, 1=3%; doubtful, 0=0%; no opinion, 0=0%.

San Antonio, Tex.—Dr. E. A. Cayo: Flat feet may be symptomless, provided the arch is not depressed to the point of supporting contact. One of the chief causes of flat foot is the natural defect of improper alignment of the leg and foot, with the result that both muscle action and gravity act to evert and depress the foot. Another cause is lack of development of foot muscles, this being due to

the wearing of shoes (any shape, continuously) during the formative period of the feet.

San Francisco, Cal.—Dr. C. H. Smith: There are numerous strong feet, flat as to imprint of sole, but not abducted on head of astragalus. These feet do not show an atrophied posterior tibial muscle nor a buckled arch.

\*Boston, Mass.—The second sentence is the exception rather than the rule.

(6)—*Flat foot signifies that ligaments and muscles have stretched at some time in the remote or immediate past. There may or may not have been subsequent restoration of muscular and ligamentous strengths, as existing strength cannot be told from appearances.*

Orthopedists agreed, 84=84%; disagreed, 13=13%; doubtful, 3=3%; no opinion, 0=0%.

Shoe dealers agreed, 31=88%; disagreed, 3=9%; doubtful, 1=3%; no opinion, 0=0%.

Hartford, Conn.—A certain amount of flat foot may be perfectly normal to a race, family, or individual.

Worcester, Mass.—I assume that "remote" may be interpreted as congenital.

New York City.—Many flat feet are congenital, especially among Negroes.

Brooklyn, N. Y.—Long Island Hospital—Agreed with first sentence, disagreed with second sentence.

Denver, Colo.—Dr. C. M. Spicer: Disagreed.

San Francisco, Cal.—Disagreed that ligaments stretch. Ligaments of white fibrous tissue and cannot stretch. They pull out of exostosis which simulates stretching.

(7)—*Causes of muscular or of ligamentous weakness many times are found in obscure defects of circulating blood, and at other times in nervous diseases that affect nerves running to foot muscles, producing weakness.*

Orthopedists agreed, 86=86%; disagreed, 2=2%; doubtful, 11=11%; no opinion, 1=1%.

Shoe dealers agreed, 27=77%; disagreed, 0=0%; doubtful, 2=6%; no opinion, 6=17%.

New York City.—Causes of weakness should include thrombosis, obliterating endarteritis, metabolic disturbances, scorbutus, rickets, osteomalacia, osteitis deformans.

Kansas City, Mo.—Dr. James R. Elliott: Focal foot infections may be causes of weakness.

\*Memphis, Tenn.—Caradine Shoe Company: Proper fitting will correct muscular trouble.

New York City.—Dr. Leo Mayer: Doubtful whether obscure defects of circulating blood are causes of muscular or of ligamentous weakness.

Toledo, Ohio.—Dr. N. J. Saybold: Say "occasionally" rather than "many" times that causes are found in obscure blood defects.

Chicago, Ill.—Occasionally, but not commonly.

(8)—*Excessive mechanical strain from overuse or injury is a very common exciting*

cause of weakness of muscles and ligaments. Slight strains acting on muscles already weakened produce effects somewhat similar to greater strains acting on stronger muscles.

Orthopedists agreed, 100=100%; disagreed, 0=0%; doubtful, 0=0%; no opinion, 0=0%.  
Shoe dealers agreed, 35=100%; disagreed, 0=0%; doubtful, 0=0%; no opinion, 0=0%.

(9)—There are long narrow feet, and short broad ones, also many minor variations in foot proportions among different individuals. All variations may be considered normal in many instances, and due to natural variations in development of bones.

Orthopedists agreed, 99=99%; disagreed, 0=0%; doubtful, 7=1%; no opinion, 0=0%.  
Shoe dealers agreed, 33=94%; disagreed, 1=3%; doubtful, 1=1%; no opinion, 0=0%.

(10)—Feet possessing average bony development and similar shape may have different degrees of efficiency however, because of differences in muscles and ligaments controlling them. Too much stress, therefore, should not be laid on ideal foot form or foot posture. Bony development does influence foot efficiency, but in ways that are difficult to estimate.

Orthopedists agreed, 94=94%; disagreed, 4=4%; doubtful, 2=2%; no opinion, 0=0%.  
Shoe dealers agreed, 31=88%; disagreed, 0=0%; doubtful, 2=6%; no opinion, 2=6%.

Cincinnati, Ohio.—Dr. R. B. Coffield: It is questionable whether too much stress can be laid on ideal foot form or foot posture.

New York City.—Disagreed that too much stress can be laid on ideal foot form or posture.

Hartford, Conn.—Dr. Robert M. Yergason: In my opinion it is fundamentally necessary to distinguish between the normal foot and the average foot. The average foot is the racial normal not that of the individual necessarily.

(11)—Feet exhibiting differences of form and posture sometimes may possess exactly the same degrees of efficiency as far as can be detected. This is due to muscles and ligaments of differing strengths acting on bones of differing development, the combined effects of bones, muscles, and ligaments equalling each other in different persons.

Orthopedists agreed, 93=93%; disagreed, 1=1%; doubtful, 5=5%; no opinion, 1=1%.  
Shoe dealers agreed, 30=85%; disagreed, 0=0%; doubtful, 1=3%; no opinion, 4=12%.

(12)—Normal foot function results from adequate exercise and adequate rest for bones, joints, ligaments, and foot muscles. When there are restrictions imposed by shoes there are slight effects produced which are not measurable in many instances.

Orthopedists agreed, 95=95%; disagreed, 0=0%; doubtful, 4=4%; no opinion, 1=1%.  
Shoe dealers agreed, 34=87%; disagreed, 0=0%; doubtful, 1=3%; no opinion, 0=0%.

Memphis, Tenn.—These slight defects may result seriously if not detected.

(13)—Prolonged disuse causes muscles and ligaments to weaken and shrink slowly. Excessive use causes them to become irritated, strained, and weakened. An alternation of exercise and rest is essential for maintenance of average strength.

Orthopedists agreed, 98=98%; disagreed, 0=0%; doubtful, 2=2%; no opinion, 0=0%.  
Shoe dealers agreed, 33=91%; disagreed, 0=0%; doubtful, 1=3%; no opinion, 1=3%.

(14)—Greatest foot strength depends on maintenance of best proportions of alternating exercise and rest, in muscles and ligaments originally well developed at birth, and on continued excellent quality of circulating blood.

Orthopedists agreed, 96=96%; disagreed, 0=0%; doubtful, 4=4%; no opinion, 0=0%.  
Shoe dealers agreed, 31=88%; disagreed, 1=3%; doubtful, 1=3%; no opinion, 2=6%.

Columbus, Ohio.—Add at end of sentence "and good sensible shoes."

Toledo, Ohio.—It is doubtful whether greatest foot strength depends on continued excellent quality of circulating blood.

(15)—Feet are adaptable. They will accommodate themselves without appreciable harm for short periods of time to ill fitting, poorly shaped shoes of various sorts, or to complete immobilization in plaster of Paris casts, or to free barefooted states.

Orthopedists agreed, 97=97%; disagreed, 1=1%; doubtful, 2=2%; no opinion, 0=0%.  
Shoe dealers agreed, 28=79%; disagreed, 4=12%; doubtful, 2=6%; no opinion, 1=3%.

Columbus, Ohio.—Ohio State University—Dr. H. Shindle Wingert: They will not accommodate themselves without considerable discomfort.

Baltimore, Md.—Dr. Sydney M. Cone: Agreed, if emphasis is laid on "short" periods.

Rawlins, Wyo.—E. Mosher: I do not believe that any foot can be put into an ill-fitting or poorly shaped shoe, and the shoe worn more than a day or two at a time without injury to the foot.

Rochester, N. Y.—Some feet will adapt themselves, not all.

West Chester, Pa.—C. O. Hoffman: Doubtful.

Memphis, Tenn.—Shoes that are too short will cause joint trouble very quickly.

Boston, Mass.—They will accommodate themselves without appreciable harm for short periods only, but harm is gradually resulting.

New York City.—Dr. V. P. Gibney: Agreed. (16)—If a single foot posture is maintained continuously without change for a very long period, then feet will adapt themselves slowly to this position until it tends to become their natural comfortable posture of repose.

Orthopedists agreed, 76=76%; disagreed, 7=7%; doubtful, 16=16%; no opinion, 1=1%.

Shoe dealers agreed, 26=74%; disagreed, 5=14%; doubtful, 3=9%; no opinion, 1=3%.  
Boston, Mass.—If you mean that had static posture of the feet may become a tolerably comfortable one after years, I agree.

New York City.—Dr. Henry Keller: Agreed, provided the wearer is very young and the bones are soft and moldable.

Detroit, Mich.—Dr. C. L. Storey: Doubtful, varies with different feet.

Chicago, Ill.—Doubtful, depends on posture assumed.

Des Moines, Ia.—Doubtful as to comfort.

Memphis, Tenn.—Dr. T. H. Ingram: Doubtful.

Boston, Mass.—Dr. R. B. Osgood: Doubtful.

Boston, Mass.—Dr. Chas. F. Painter: Say "feet may adapt themselves" rather than "feet will adapt themselves," then I agree.

Brooklyn, N. Y.—Agreed if the foot posture is a good one, otherwise disagreed.

Milwaukee, Wis.—S. J. Brouwer, of The S. J. Brouwer Shoe Company: I presume that a posture of repose would mean a Chinese woman sitting still. For maximum, full, efficient strength we need to restore the foot to normal.

(17)—Painless deformities of variable degrees may develop in this manner from the continuous wear of a single size and shape of shoes. Bones slowly change their shapes. Some muscles and ligaments stretch while others shorten naturally until unequal pressures and strains are brought finally into a state of equilibrium in the selected fixed posture.

Orthopedists agreed, 82=2%; disagreed, 9=9%; doubtful, 7=7%; no opinion, 2=2%.  
Shoe dealers agreed, 28=79%; disagreed, 4=12%; doubtful, 1=3%; no opinion, 2=6%.

New York City.—Dr. T. Halsted Myers: Disagreed.

Chicago, Ill.—Painless for a time.

Los Angeles, Cal.—Disagreed.

Rochester, N. Y.—Agreed, generally, yes.

Hartford, Conn.—Ligaments do not stretch but pull the periosteum from the bone, giving pain. The bone then grows into the space under the elevated periosteum. Thus arise deformities of bones which gradually alter their shapes. Ligaments will tear before they will stretch.

(18)—There is no single ideal shape or style of shoes that is best continuously for all foot conditions.

Orthopedists agreed, 90=90%; disagreed, 7=7%; doubtful, 1=1%; no opinion, 2=2%.  
Shoe dealers agreed, 31=88%; disagreed, 1=3%; doubtful, 1=3%; no opinion, 2=6%.

Muskegon, Mich.—Louis P. Haight: I believe that there should be a single shape or style of shoe, and that all shoes which do not agree with this standard shape are incorrect; in other words, there can be but one correct measurement of anything, and that shoes which have been manufactured thus far have been made for style and sale rather than from anatomical lines. There should be a standardization of American shoes.

(19)—Many shapes, proportions, and sizes of shoes are needed at times to fit the many shapes, proportions and sizes of feet.

Orthopedists agreed, 94=94%; disagreed, 4=4%; doubtful, 0=0%; no opinion, 2=2%.  
Shoe dealers agreed, 32=91%; disagreed, 1=3%; doubtful, 0=0%; no opinion, 2=6%.

Sacramento, Cal.—Dr. J. M. Crawford: Disagreed.

Chicago, Ill.—Dr. Schenkellberger: I am inclined to place more blame on poorly shaped and badly fitted shoes than on Nature and lack of proper foot development. Development is hampered by bad shoes even before the child is two years old. Tiny baby shoes are made at least one-quarter of an inch wider at the heel than any normal baby's foot, and there is absolutely no fit in the arch. The trend is either very wide or the shoe fitted too short. Parents should no more think of buying pointed toed shoes for a growing child than they would adopt a square fingered glove for the hand or a three-cornered hat for the head.

Worcester, Mass.—There is a limit that can be reached beyond which the study of shoes possesses but slight merit.

Brooklyn, N. Y.—Dr. Truslow: Suggests a temporary "treatment" shoe for use while temporary apparatus is being worn. It would allow comfort while feet were being padded and strapped, while wearing insole supports with metatarsal pads, and while having convalescent dressings after surgical care. He suggests (a) as its ground plan—sole, shank, heel one that is similar to best foot shaped lasts available now with stiff shanks. (b) More front vamp room, i. e., more upper leather from side to side from of toes forward. (c) Soft vamp with no boxing.

Pittsburgh, Pa.—Dr. E. W. Fiske: States there are two important points which should be put up to the shoe man. (1) The principles of a good shoe, namely, straight line inside or in flare and outflare on prescription from orthopedic surgeon. Good toe room and anterior foot space. Relatively snug heel and instep. (2) Recognition of the pathological foot by shoe fitters. Condemnation of store arch supporters and store doctors. Serious disabilities following lay advice and treatment of flat foot. Realization that a shoe seldom more than aids a pathological foot, that feet should be measured for relief carefully as eyes are, and treated by orthopedists.

(20)—Shoes have to be adapted to feet in some instances, while feet must be adapted to shoes at other times.

Orthopedists agreed, 74=74%; disagreed, 17=17%; doubtful, 6=6%; no opinion, 3=3%.

Shoe dealers agreed, 23=65%; disagreed, 6=17%; doubtful, 3=9%; no opinion, 3=9%.

Pittsburgh, Pa.—Agreed that poor feet may need to be adapted to good shoes at times.

Boston, Mass.—F. W. Small, Gilchrist Company: Deformed conditions may be slightly bettered by improved shapes of shoes.

New York City.—Shoes, like braces, should be applied after correction of deformity in order to retain shape, and not for correction.

New York City.—Dr. Armitage Whitman: Disagreed.

Cincinnati, O.—Dr. Albert H. Freiberg: Disagreed.

San Antonio, Texas.—This is absolutely all wrong.

Muskegon, Mich.—If feet are sore they should be corrected before being fitted to any kind of shoes.

(21)—Shoes have to be adapted carefully to feet that are very sore or weak. Deformed, symptomless strong feet should be adapted gradually to improved shapes of shoes. Compromises between these two methods must be made frequently when complete lines of shoes are not available.

Orthopedists agreed, 91=91%; disagreed, 4=4%; doubtful, 2=2%; no opinion, 3=3%.

Shoe dealers agreed, 28=79%; disagreed, 1=3%; doubtful, 2=6%; no opinion, 4=11%.

New York City.—Disagreed that deformed, symptomless strong feet should be adapted to improved shoes.

St. Johnsburg, Vt.—Amey & Reed: I question the advisability of changing the shape in a deformed nature shoe, if it is strong.

(22)—Several pairs of shoes of slightly different shapes, sizes and balance are better to wear than a single fixed style continuously if the person is in good health and has normal, adaptable feet.

Orthopedists agreed, 39=39%; disagreed, 33=33%; doubtful, 26=26%; no opinion, 2=2%.

Shoe dealers agreed, 15=43%; disagreed, 15=43%; doubtful, 3=8%; no opinion, 2=6%.

Greenberg, Ind.—Roy C. Kanouse: Wear one style.

Boston, Mass.—The shape and proportion best adapted should be generally worn.

Fort Worth, Tex.—R. M. Logan, Mosher Brothers: Disagreed.

Memphis, Tenn.—Not without pain.

Rochester, N. Y.—If the shape and style is right then several pairs of the same kind are all right.

San Antonio, Tex.—Dr. Cayo: This is as free from scientific expression as a frog from feathers.

Louisville, Ky.—Dr. B. S. O'Brien: Disagreed.

Cambridge, Mass.—Dr. W. J. LaMarche: The individual foot has always the same shape. Why change it by prescribing different shapes of shoes?

Washington, D. C.—Dr. C. L. Hall: Agreed.  
Boston, Mass.—Dr. H. W. Marshall: Several pairs of shoes of slightly different balance, of different degrees of snugness, of different shapes, of different degrees of flexibility, will tax the feet more than a single style. A young woman who wears at appropriate times sensible foot shaped lasts, heelless, flexible sporting shoes, and high heeled pumps in turn subjects her feet to increased tasks that are beneficial as long as they are not too great, and if they assist in retaining foot adaptability. She will not suffer if she attempts to walk without shoes, as some persons do who

have been propped up continuously for long periods in stiff shanked, good shaped, snugly fitted, very comfortable shoes. There is possibility of enjoying too great and too continuous comfort. Do not let the feet lose their adaptive powers. Let people wear different shoes if they can for exercise as well as for corrections of supposed foot defects. To make such changes of footwear, however, after the person has been long accustomed to a single type and size usually is a very difficult task and should be undertaken very gradually, if at all. A barefooted savage subjects his feet to conditions, many of which would be quickly harmful if maintained continuously, yet continual changes of all sorts tend to keep his feet in best condition.

*Milwaukee, Wis.*—S. J. Brouwer Shoe Company: Normal, adaptable feet do not last a lifetime if shoes are worn that vary in size, shape, and balance to any appreciable extent. If such a doctrine were preached to the general public, too many would be prone to wear shoes too small for them.

(23)—A healthy young adult can wear without harm for very brief intervals, almost any shoe shape or height of heels, and when this capacity begins to be lost then old age is creeping on, or muscles and ligaments are weakening from some other cause, or local disease processes are developing in bones or joints of the feet.

Orthopedists agreed, 70=70%; disagreed, 16=16%; doubtful, 10=10%; no opinion, 4=4%.

Shoe dealers agreed, 24=68%; disagreed, 7=20%; doubtful, 1=3%; no opinion, 3=9%. Cincinnati, O.—Potter Shoe Company: Agreed for very brief intervals.

\*Rochester, N. Y.—Agreed if size and fit are all right.

\*Memphis, Tenn.—Continuous abuse will produce premature aging of the feet.

Worcester, Mass.—Dr. F. W. George: I believe this statement is too broad.

Indianapolis, Ind.—Dr. E. B. Mumford: Disagreed.

Kansas City, Mo.—Dr. J. D. Griffith: Doubtful.

Columbus, O.—Dr. Wingert: Positively no.

\*Milwaukee, Wis.—I know from actual experience that disease tends to settle in parts where wrong shapes and wrong heels have been used, even for a short period. People grow old earlier because of improper body balance, resulting from shoes not built correctly on the inside as to the lines of the inner sole following the contour of the arches.

(24)—Flexible shanked shoes are best usually for strong, symptomless feet because they permit most exercise.

Orthopedists agreed, 82=82%; disagreed, 8=8%; doubtful, 8=8%; no opinion, 2=2%.

Shoe dealers, agreed, 26=74%; disagreed, 4=12%; doubtful, 5=14%; no opinion, 0=0%.

\*Rochester, N. Y.—Agreed for strong symptomless feet. Flexible shoes otherwise are very harmful and dangerous.

Brooklyn, N. Y.—Agreed unless the individual is very heavy.

Hartford, Conn.—Dr. Ansel G. Cook: I have no objection to flexible soled shoes such as moccasins for normal feet, but when you put a heel, any kind of a heel, on a shoe with a flexible shank you have disturbed the balance and thrown an added pressure on the longitudinal arch of the foot. Some feet are strong enough to bear this added strain and some are not. Some people with very broad, short feet, do not require, in fact, cannot wear a shank. In such cases a broad, low heel gives all the support required. With this exception all shoes that have heels should also have adequate shanks.

Denver, Colo.—Dr. S. Fosdick Jones: Personally, I do not approve of flexible shanks either for deformed or normal feet.

(25)—Stiff shanked shoes are best usually for delicate persons whose foot muscles and ligaments never acquire average degrees of strength, or for those with disease in bones of the feet.

Orthopedists agreed, 79=79%; disagreed, 9=9%; doubtful, 7=7%; no opinion, 5=5%.

Shoe dealers agreed, 29=82%; disagreed, 4=12%; doubtful, 2=6%; no opinion, 0=0%.

\*Memphis, Tenn.—Stiff shanked shoes are especially good for advanced age and increased weight.

\*Rochester, N. Y.—Wm. Pidgeon: Stiff shanked shoes if properly fitted are all right for everyone.

\*Muskegon, Mich.—A stiff shanked shoe which will hold such a foot in position would tend to weaken rather than strengthen it, and I should prefer strengthening the muscles and putting such a foot into a standard shoe.

Chicago, Ill.—Stiff shanked shoes are best for a time until muscles can be built up.

Atlanta, Ga.—Doubtful whether stiff shanked shoes are best usually for persons with disease in bones of feet.

San Francisco.—Dr. Hunkin: I do not think a definite statement can be made in such manner.

Chicago, Ill.—Dr. F. C. Text: Agreed, splints, in other words.

Pasadena, Cal.—Dr. Wm. A. Clark: Doubtful.

\*Milwaukee, Wis.—I would add that stiff shanks are for rest purposes only. Stout people frequently come in this class. I would not put a rigid shank on a delicate person whose foot muscles and ligaments have only average strength, but instead would use flexible shank shoes in which the uppers act like a bandage.

(26)—There are many degrees of flexibility and stiffness of shanks, and an individual should wear as flexible footwear as his foot strength at any specified time will permit. He may wear stiff shanked shoes for brief periods with advantage when feet weaken for brief periods. He may wear flexible shoes continuously if his foot strength remains adequate continuously.

Orthopedists agreed, 85=85%; disagreed, 11=11%; doubtful, 1=1%; no opinion, 4=4%.

Shoe dealers agreed, 22=63%; disagreed, 8=23%; doubtful, 5=14%; no opinion, 0=0%.

\*Lincoln, Neb.—Budd Shoe Company: Disagreed.

\*Dallas, Tex.—Volk Brothers Company: Doubtful.

Nashville, Tenn.—Dr. R. W. Billington: The shank of the foot touches the sole of the foot only along its outer border; and does not support the long arch or prevent pronation or strain on the arch, no matter if the shank is stiff. Support of this arch depends on a broad, long heel built up at front and inner corner. This gives support directly, also indirectly, by preventing pronation. An additional help is a narrow shank well curved or cut under at the right border. A broad, stiff shank serves as a stiff board to which the foot is strapped and thus flattened as the shoe is laced.

Boston, Mass.—Dr. H. W. Marshall: Some persons reason that, if a flexible shoe is right, then a stiff shoe is wrong. This may be a logical conclusion, but physiological peculiarities of muscles rather than logic determine whether flexible or stiff shoes are better. Muscles vary in development as much as bones. Some are weak. The same muscles in other individuals are very strong. Rarely some muscles may be entirely missing, while in other instances unusual accessory muscles are developed. Therefore, some persons have congenital tendencies toward foot weakness or great foot strength. All muscles will grow stronger with proper use up to a certain limit, but this can be, and often is, exceeded. The limit is much greater for large muscles than for congenitally small ones. When the limit, whatever it is, is exceeded, there should be given support to the strained muscles until means are found for reducing the demands made on them. Adhesive strappings properly applied are superior to all other means for slight strains of comparatively brief duration. Carefully graduated exercises in some form generally should be provided after the vacations for muscles by strappings have been terminated. Many non-medical men and a few orthopedists apparently do not realize fully that without appreciable change of habits, without injury or increased use of the feet, muscles may slowly weaken under subtle undermining vascular and nervous influences. A person may be well fitted with flexible shoes at one time, while several months later, for no very obvious reason except perhaps slight debility, and slight loss of weight, some form of support is found best, temporarily. The latter needs in turn may be replaced after a longer or shorter period by new ones. Muscular strength and tone shift from time to time, yet always tend to settle into a state of equilibrium that is calculated to fit the individual's particular requirements at the given period.

(27)—Feet can serve as indicators of health. In modern complex life there are noticed many individuals with recurring mild, short attacks of foot strain. Foot conditions roughly fluctuate with states of a person's health. The step is elastic, light, firm and brisk in good health. It is less elastic, heavier and slower as debility comes on and as definite foot weakness appears.

Orthopedists agreed, 92=92%; disagreed, 1=1%; doubtful, 6=6%; no opinion, 1=1%.

Shoe dealers agreed, 31=88%; disagreed, 2=6%; doubtful, 2=6%; no opinion, 0=0%.

Worcester, Mass.—In many but not all cases of ill health.

\*Hutchinson, Kas.—Some people have bad feet, but are perfectly healthy.

(28)—Removable foot supports for longitudinal arches possess important advantages

in being easily regulated in their use. They permit support in mild cases of foot strain for brief periods, and need not be worn too long, as may happen more frequently if stiff, shanked shoes alone are relied on without other types to change to.

Orthopedists agreed, 78=78%; disagreed, 12=12%; doubtful, 7=7%; no opinion, 3=3%.

Shoe dealers, agreed, 25=72%; disagreed, 5=14%; doubtful, 5=14%; no opinion, 0=0%.

New York City—Agreed theoretically, but most people wear them all of the time or not at all.

Philadelphia, Pa.—Dr. Rugh: I use these supports only for relief of pain which will not yield to balanced shoes.

San Francisco, Calif.—Dr. A. L. Fisher: I believe that all stiff shanks and all plates are to be avoided excepting possibly Whitman plates.

Des Moines, Iowa—Properly fitted shoes and exercises are better.

Oakland, Calif.—Dr. N. Austin Cary: Opinion depends on type and construction of arches used.

Cleveland, Ohio—Dr. Gordon N. Morrill: I do not use plates for any but the anterior arches, and have found much to my relief and to my patients' relief, that teaching them how to stand and to walk is 99 per cent of the game.

\*Rochester, N. Y.—It all depends on what kind of stiff shanks are worn.

\*Muskegon, Mich.—I have found that the cause of longitudinal arch trouble is almost always due to turning out of the feet thereby stretching the muscles.

\*Chillicothe, Ohio—Herman Brothers: At least a dozen representatives are building so-called arch support shoes, and most of them have merit. Supports can be built in several types of lasts, which I think is correct, as it does not compel different styles of feet to conform themselves to the swing last or extreme broad shank. One may be correct in one instance and wrong in another.

Kansas City, Mo.—Dr. Robt. McE. Schaeffer: Agreed, with reservations as to the kind of support.

\*Milwaukee, Wis.—If a person is selling all sorts and shapes and kinds of shoes, and merely wants to "get by," merely removable supports will answer; but, from my experience, I feel that where shoes are built anatomically correct as far as the shape and contour of the inner sole are concerned, people ought not to be abused with extra supports shoved into shoes that are incorrect in their alignment.

(29)—Removable supports can be inserted in flexible shoes, converting them into stiff shanked types temporarily, and thus extending the limits of range of flexibility and stiffness obtainable with a single pair of shoes. By grading amounts of support by numbers of hours that supports are worn daily, transitions can be made gradually and conveniently from one type to the other.

Orthopedists agreed, 76=76%; disagreed, 15=15%; doubtful, 5=5%; no opinion, 4=4%.

Shoe dealers agreed, 19=54%; disagreed, 6=17%; doubtful, 5=14%; no opinion, 5=14%.

Philadelphia, Pa.—Dr. Arthur J. Davidson: It can be done but it is advisable?

Iowa City, Iowa—Dr. A. Steindler: No flexible shanks for the uncompensated foot.

San Francisco, Cal.—Dr. G. J. McChesney: I consider arch supports unnecessary. Lessen the load on the arch and strengthen the arch supporting structures. I throw the weight toward the outer side of the foot by built up shoes, correct the posture in walking, and give exercise to strengthen the tibial muscles. When this is not enough to correct the condition, rest in bed and plaster splints are indicated.

San Francisco, Cal.—Absurd to put supports in flexible shoes.

Kansas City, Mo.—Dr. James R. Elliott: I do not use rigid supports.

New York City—These cases should have padded insoles instead of stiff metal plates.

Birmingham, Ala.—Dr. E. L. Scott: Disagreed.

Rochester, N. Y.—Disagreed, the heel and ball will pull apart, and that ruins the foot.

Los Angeles, Cal.—Dr. Lowman: This is misleading in that such a course might lead many patients to keep on wearing an old flexible pair of shoes bought early in the course of treatment, which represent more or less their old faulty condition. I agree that the transition can be made gradually from a stiff to a flexible shoe, but it should be understood that the shoe is of an entirely new type which represents an advance. The gradation should be one of going from arch plates to stiff shank shoes, and later from stiff shank shoes to flexible shoes if desired.

(To be continued)

# Sanitation in National Parks and Monuments

## Careful Inspection and Regulations Protect Tourists to National Parks

BY H. B. HOMMON, SANITARY ENGINEER, U. S. PUBLIC HEALTH SERVICE, WASHINGTON, D. C.

THERE are seventeen national parks, and twenty-four national monuments in the United States proper, and two parks in the possessions that are under the supervision of the National Park Service. In 1916, the number of visitors to thirteen of the parks was 356,000; a year later this number increased to 811,500 for sixteen parks and six national monuments; in 1920, the visitors to seventeen parks and eleven monuments numbered more than a million; and at the end of the season for 1921 the total registration for eighteen parks and thirteen monuments was almost one and one-quarter millions.

The Director of the National Park Service, commenting in his annual report for 1921 upon this remarkable increase, states that it was due to the World War and further "that when the conflict was successfully ended and the time had come for recuperation, tired minds and bodies turned to the national parks. At once, park travel leaped to unprecedented figures. Our tourist facilities were overwhelmed, but still the crowds came. The travelers returned refreshed, rejuvenated, better men and women from their visits to the great open breathing spaces, and returning they inspired others with the lure of the parks and their sublime scenes." The tide of tourist travel which formerly flowed toward foreign lands was stopped during the war and for a short time after the armistice and it has now turned to the national parks and monuments of our own country.

In the earlier history of the national parks, practically all the tourists came by train to the nearest adjoining cities or towns and from these points were carried through the parks in horse-drawn vehicles. During recent years, however, private automobile parties, encouraged by improved highways, have been coming to the parks in large numbers. The registration the past season shows that 65 per cent of all visitors to the parks and monuments came in private automobiles, and about one-half carried their own camping equipment. This feature of park travel has complicated the problems of park man-

agement, especially those relating to sanitation.

Before the advent of the automobile traffic in the parks, the visitors who went to the parks by train were comparatively few in number and they did not range far from the point of special interest. Recently, however, the private automobile parties and the increase in travel by trains have changed the old order and we now find the visitors frequenting all parts of the parks. This is highly desirable for it permits the people to see more of the scenery and treasures of the parks than ever before, but it has introduced problems of camp sanitation that formerly did not exist such as securing ample and pure water supplies, disposing of garbage and sewage, and inspection of food supplies.

The Director of the National Park Service, recognizing the problems of sanitation introduced by the private automobile and the general increase in travel to parks by trains, and having no trained personnel to take care of this work, requested that the Surgeon General of the United States Public Health Service detail a sanitary engineer to the Park Service to cooperate with the superintendents of the various parks and monuments in improving sanitation. The writer was assigned to this work in the spring of 1921 and during the year most of the larger parks were visited.

The investigations made last summer showed that, while all the parks have the same general problems of sanitation, each has one or more that is of particular importance. The pictures show the differences in location and character of various places in the parks where proper sanitation must be provided; the sewage treatment plant at Yosemite National Park; and the method of getting water for all purposes to the El Tovar Hotel and administration headquarters of the Grand Canyon. The reports of the investigations indicated the improvements which should be made and a brief summary of all the recommendations will indicate the methods that are to be followed in the parks in handling the various problems of sanitation.

*Water Supplies.*—Field surveys of the sources of all drinking water supplies will be made and also bacteriological analyses where there is doubt about the quality of the water. Watersheds which are sources of supplies will be posted and no trails or camping parties permitted on them, and storage reservoirs will be protected from contamination.

*Milk and Food Supplies.*—Regular inspections will be made of dairies selling milk inside the parks and of all places handling food. In some of the parks the milk is produced inside the boundaries while at others it is

Sewage treatment plant in Yosemite National Park showing Imhoff settling tank in foreground, three sections of sludge beds and ten acres of natural filter beds.

Water tank cars for hauling water ninety-eight miles from Flagstaff, Arizona, to the Grand Canyon National Park. No water is available on the top rim of the Canyon.

shipped in. At many of the parks, the food must be carried long distances in trucks and careful supervision will be maintained to see that it is delivered in proper condition.

*Sewage Disposal.*—Sewage treatment plants will be installed wherever there is a sewerage system and sewage is polluting a body of water that is used for drinking purposes. Sterilization will be included under certain conditions. A sewage treatment plant will be placed in operation this year to treat all the sewage from the floor of the valley at Yosemite National Park, and at Yellowstone several new plants will be in operation this season at different places in the park.

*Garbage Disposal.* — The present method of disposing of garbage in most of the parks is to haul it to dumps located in out of the way places. Bears frequent the dumps for food and they furnish one of the interesting sights of the parks. This method is satisfactory where the season is only about 90 days long, and when the dumps are far enough away so there are no nuisances from flies and odors at the camps and hotels. At some of the parks, however, incinerators will be required in the near future.

*Government Automobile Camp Grounds.*—Visitors traveling to the parks in their own automobiles either camp on grounds set apart by the superintendents of the parks, or they stay in hotels or camps operated by private companies. Last season 50 per cent of the visitors who came to the parks in their own automobiles carried their own camping equipment.

Practically all the camping grounds

in the parks have an ample supply of pure running water. Garbage cans are provided in the larger camps but for the smaller ones garbage is buried in pits dug at the edge of the camps. Where sewerage systems are not available, the common outside privies are used. They have been the source of much trouble in the past and the following recommendations have been made for their supervision this coming season. (1) Appoint an inspector, preferably, an active laborer, to look after each camp ground with special reference to the privies. (2) Spray

the entire contents under the privy seats twice a week with a 3 per cent solution of compound cresol solution. (3) Keep the earth banked up around the privy buildings to prevent flies from reaching contents of the vaults.

*Mosquito Control.*—The species of mosquitoes that carry malaria or other diseases have never been found in any of the national parks but the others have caused considerable annoyance. Mosquitoes have been practically eradicated from Yosemite National Park by drainage work and oiling and active operations along these lines will be undertaken in other parks this season. The greatest handicap now existing in the control of mosquitoes is the lack of funds for drainage and other work to destroy breeding places.

The superintendents of the various parks and monuments thoroughly appreciate the importance of the problems of sanitation and they have co-operated heartily in carrying out the recommendations made for improvements. Except in a very few cases, Congress has as yet provided only very meager funds for improving water supplies and disposing of sewage and garbage and the Park Service deserves much credit for the excellent work done with the small amount of money that has been available. If the rate of increase in travel of the past few years continues in the future, it will be essential that the ap-

The automobile, bringing tourists in larger numbers each year to the National parks, has greatly increased the sanitary problem. The Government maintains camping grounds for the automobilist at various points, the one pictured being in Mount Rainier National Park, Montana.

A camp amid giant sequoias, Sequoia National Park, California. Aside from insuring a safe water supply, an adequate sewage and garbage disposal, government sanitary engineers are eradicating the mosquito.

propriations for the various parks be sufficient to provide ample and pure water, and to remove and properly dispose of sewage and all other liquid and solid wastes from the hotels and camps.

Last season almost one and one-quarter million people visited the national parks and monuments and this year the total number may be in-

creased to one and one-half million. These people are the guests of the Government while in the parks, and it should be the duty of the Government to provide all the facilities necessary to protect their health. For the present, the parks are in excellent sanitary condition but this condition cannot long be maintained unless improvements are made.

## The New Dentistry Act

BY OUR LONDON CORRESPONDENT

ENGLISHMEN and English women have been notorious for their carelessness as regards the condition of their teeth and gums. The war, to a large extent, has changed the situation in this respect. Examination of those volunteering and conscripted for the army revealed an almost appalling state of affairs so far as oral hygiene was concerned. The fact was recognized by the medical profession that steps must be taken promptly to place the mouths of the English population, and especially of the working classes, in as aseptic condition as possible, although the menace of pyorrhea, alveolitis, carious teeth and so on, might be exaggerated, they certainly were causes of much ill health. However, many difficulties beset the paths of personal hygienic reformers in this direction, not the least of which was that the supply of dentists was extremely limited, and of skilled dentists in partic-

ular. Consequently, the Dentist's Act was drawn up and passed, and has now been working for about five months.

The Dentist's Act came into existence last summer and was designed to do two things, which are one and the same, namely, to provide an adequate supply of properly trained dentists to meet an admitted shortage; and secondly, to put an end to the cruelties and extortions which were marking the procedure of many quacks. It may be pointed out once more that the main provision of the Act was to legalize by legislation the professional services of a large body of men who had previously practised dentistry without qualification and no doubt dentists who were registered already viewed with mixed feelings the dilution of their small body—about four thousand—with perhaps ten thousand whose equipment was vouched for by no standardizing examinations.

The regulations were not approved definitely until the end of last January. In the three months which have elapsed since the actual applications received numbered 6,765, which may be analyzed as follows: 4,294 from claims as practitioners during five of the past seven years; 1,551 from members of the incorporated Dental Society; 423 from mechanics; 271 from persons in practice at the time of the passage of the Act but who, like mechanics, have to pass an examination before registration; and 226 from chemists having a substantial practice as dentists at the commencement of the Act. The speed at which the new Register is being made up is shown by the fact that of the 6,765 applications, more than four thousand proved satisfactory, 2,200 of these being persons who had been in practice for five of the past seven years, and 1,400 being members of the Incorporated Dental Society.

The business of the Dental Board is not only to prohibit the practice of dentistry by unregistered persons, but also to see that those who are registered comply with the provisions of the Act. That the Board is alive to its duties as shown by the fact that already it has had before it the names of twenty persons who are alleged to have infringed the regulation dealing with the employment of unqualified assistants. A warning has been issued to registered dentists pointing out that the employment by them of an unqualified assistant in respect of matters requiring professional discretion or skill renders them liable to erasure from the Register; but in regard to this matter there seems to have been much misapprehension.

In order to understand the situation properly attention may be brought to the point that there are two methods in which unqualified assistants may be improperly employed: (1) the opening of a branch practice and the placing of an unqualified employee in its charge; and (2) the employment of the unqualified person on the main premises. A dentist should be adequately qualified from every point of view to do the important work effectively. He should be scientifically as well as mechanically equipped, and it is a wise procedure on the part of the powers that be in Great Britain to cause laws to be enacted which will accomplish this object.

A recreation congress called by the Playground and Recreation Association and Community Service will be held in Atlantic City, October 9 to 12.

# Report of Committee on Nursing Education\*

THE Committee which presents the following report was first appointed by the Rockefeller Foundation in January, 1919, to conduct a study of "the proper training of public health nurses."

It was, therefore, the pressing need for more, and for better, nurses in the field of public health that first suggested the desirability of such an investigation. It soon became clear, however, that the entire problem of nursing and of nursing education, relating to the care of the sick as well as to the prevention of disease, formed one essential whole and must be so considered if sound conclusions were to be attained. A year later, in February, 1920, the Foundation requested us to broaden the scope of our inquiry to include "a study of general nursing education, with a view to developing a program for further study and for recommendation of further procedure." "We have attempted therefore to survey the entire field occupied by the nurse and other workers of related type; to form a conception of the tasks to be performed and the qualifications necessary for their execution; and on the basis of such a study of function to establish sound minimum educational standards for each type of nursing service for which there appears to be a vital social need.

Since it was the obvious need for more adequate nursing service in the field of public health which brought to a head the demand for a comprehensive study of nursing education—long felt and first voiced by the official organization of nurses—it seems natural to begin with a consideration of this phase of the broader problem.

It is obvious that the public health movement has passed far beyond its earlier objectives of community sanitation and the control of the contact-borne diseases by isolation and the use of sera and vaccines. Many major health problems of the present day, such as the control of infant mortality and tuberculosis, can be solved only through personal hygiene—an alteration in the daily habits of the individual—and through the establishment of new contacts with the public

—contacts which shall permit the application of the resources of medical science at a stage in disease when they can produce a maximum effect. Such changes in the daily habits of the people and in their relation to their medical advisors, can be accomplished by but one means—education. In its present phase of emphasis on personal hygiene, the public health movement has thus become during the past two decades preeminently a campaign of popular education.

## The Nurse in Public Health

The new educational objectives of the health administrator may be approached to a limited extent by mass methods. The printed page, the public lecture, the exhibit, the cinematograph, the radiogram, help to prepare the ground and to make success easier. The ultimate victory over ignorance is, however, rarely attained in such ways. Direct personal contact with the conditions of the individual life is essential to success in a matter so truly personal as hygiene. We have sought during the past twenty years for a missionary to carry the message of health into each individual home; and in America we have found this messenger of health in the public health nurse. In order to meet generally accepted standards we should have approximately fifty thousand public health nurses to serve the population of the United States—as against eleven thousand now in the field. All public health authorities will probably agree that the need for nurses is the largest outstanding problem before the health administrator of the present day.

In view of this fact, public health authorities, both in this country and abroad, have naturally considered the possibility of finding a short way out of their difficulties by the employment of women trained in some less rigorous fashion than that involved in the education of the nurse. It was therefore to the question of the necessary and desirable equipment of the teacher of hygiene in the home that we first directed our attention. There are at present two distinct types of public health nursing practise in the United States—that in which the nurse confines herself to the teaching of hygiene, and that in which such instructive work is combined with the actual care of the sick. A third type of visiting nursing, in which bedside care is given with no educational

service, may be observed in individual instances. It results, however, from temporary limitations rather than considered policy, since practically all visiting nurse associations, in theory at least, stress hygienic education in their official program.

The question whether the public health nurse should or should not also render bedside care has been hotly debated during the past few years. The arguments for purely instructive service rest mainly on two grounds, the administrative difficulties involved in the conduct of private sick nursing by official health agencies and the danger that the urgent demands of sick nursing may lead to the neglect of preventive educational measures which are of more basic and fundamental significance. Both these objections are real and important ones. Yet the observations made in the course of our survey indicate that both may perhaps ultimately be overcome. Several municipal health departments have definitely undertaken to provide organized nursing service for bedside care combined with health teaching, while in other instances instructive nurses, under public auspices, combine a certain amount of emergency service with their fundamentally educational activities. So far as the neglect of instructive work is concerned it results from numerical inadequacy of personnel and can be avoided by a sufficiently large nursing staff.

On the other hand, the plan of instructive nursing divorced from bedside care suffers from defects which if less obvious than those mentioned above are in reality more serious, because they are inherent in the very plan itself and therefore not subject to control. In the first place—the introduction of the instructive but non-nursing field worker creates at once a duplication of effort since there must be a nurse from some other agency employed in the same district to give bedside care. In the second place, the field worker who attempts health education without giving nursing care is by that very fact cut off from the contact which gives the instructive bedside nurse her most important psychological asset. The nurse who approaches a family where sickness exists, and renders direct technical service in mitigating the burden of that sickness, has an overwhelming advantage, then and thereafter, in teaching the lessons of hy-

\*The report as published herewith in full is signed by the Committee, as follows: C.-E. A. Winslow, chairman, Mary Beard, Hermann M. Biggs, S. Lillian Clayton, Lewis Conner, David L. Edsall, Livingston Farrand, Annie W. Goodrich, L. Emmett Holt, Julia C. Lathrop, Isabel W. Lowman, M. Adelaide Nutting, C. G. Parnall, Thomas W. Salmon, Winford H. Smith, E. G. Stillman, Lillian D. Wald, William H. Welch, and Helen Wood.

giene. With an adequate number of nurses per unit of population, we believe that the combined service of teaching and nursing will yield the largest results. Nurses employed by state health departments and others whose work is largely stimulative and supervisory in nature may not of course be in position to render direct bedside care.

### Nurse Best Health Educator

There are other messengers who may be sent into the field to fulfil other functions. The task of the trained social worker for example is to diagnosticate and repair maladjustments in social relationships, a correlated but quite distinct vocational field. Even public health agencies may employ other field workers of an allied type, such as clinic messengers. It is obvious, however, that where health instruction is combined with bedside care the fully trained nurse is the only possible type of health educator; and such a combination represents the one type of service which it is feasible to supply in rural districts. Even purely instructive work if conducted on the generalized district plan, calls for an ability to detect the early signs of contagious disease, to discern symptoms which suggest tuberculosis, to give counsel as to infant care or the feeding of older children, which can scarcely be attained without a wide training. The relative lack of nursing personnel in Europe has there led to the attempt to train health visitors of the purely instructive type for dealing with special individual problems, such as tuberculosis or child welfare, by training courses much shorter than those required for the preparation of the nurse. Opinion as to the result of such experiments in Europe varies widely; but for conditions as they exist in the United States we are convinced that the teacher of hygiene in the home should be equipped with no less rigorous training than that accorded to the bedside nurse, further supplemented by special studies along the lines of public health and social service.

That an improvement in quality, as well as an increase in the number of public health nurses is fundamental to the complete success of the public health movement, is a point on which we find all competent authorities to be substantially agreed. Miss Goldmark's report of an intensive study of the daily work of 164 public health nurses, representing forty-seven different organizations, gives glimpses of women whose constructive

service and compelling personal inspiration seem to touch the highest possibilities of social achievement. Such a nurse establishes herself in the confidence of her community, so that she becomes its trusted advisor and best friend, caring for the sick, securing medical aid, counseling as to hygiene, resolving difficulties of a hundred sorts with the touch of a practiced hand.

Nearly half of the nurses observed in our survey were classed as definitely successful in their work and less than one-fourth as definitely unsuccessful—a showing perhaps better than would be made by a random sampling of most professions. Yet it remains true that either from a lack of knowledge of preventive measures or of teaching methods, from failure to effect contact with physicians or with social agencies, a substantial proportion of public health nurses do fail to realize the possibilities of their profession. Administrative policies, overloading, and inadequate supervision, are sometimes at the root of the trouble; yet it is obvious that such a calling as public health nursing demands in the first place a high degree of natural capacity and in the second place a sound and a broad education.

### Essential Qualifications

We are convinced, therefore, that the teacher of hygiene in the home should possess in the first place the fundamental education of the nurse and that this should be supplemented by a graduate course in the special problems of public health. The latter point will be discussed in detail in a succeeding paragraph but we believe that the general considerations so far discussed warrant the following conclusion:

*Conclusion 1.—That, since constructive health work and health teaching in families is best done by persons: (a) capable of giving general health instruction, as distinguished from instruction in any one specialty, and (b) capable of rendering bedside care at need, the agent responsible for such constructive health work and health teaching in families should have completed the nurses' training. There will of course be need for the employment in addition to the public health nurse of other types of experts such as nutrition workers, social workers, occupational therapists, and the like.*

*That as soon as may be practicable all agencies, public or private, employing public health nurses should require as a prerequisite for employment the basic hospital training, followed by a post-graduate course, in-*

*cluding both class work and field work, in public health nursing.*

Before considering the basic demand for nurses to function in the routine care of the sick we must point out that it is by no means only in the field of public health nursing, that the need for women of high natural qualifications and fundamental training is now manifest. The modern hospital and the modern dispensary represent social forces of enormous and growing magnitude. The technical complexity of their operation increases with every passing year; and, aside from the problem of the staff nurses required for the ordinary routine of such institutions, which will be discussed in a succeeding paragraph, there is perhaps no more urgent problem for the hospital administrator than that of obtaining nursing superintendents and supervisors adequate for the performance of their difficult tasks. The development, both of public health nursing and of administrative hospital nursing, involves and demands a corresponding development in nursing education which constitutes another inviting field for women.

The defective preparation and qualifications of many instructors in schools of nursing in both practical and theoretical branches is very marked. Yet in the training school the instructor is often called upon to teach six or eight different subjects, far more than would be demanded even of the teacher in a country high school. It should be noted, however, that the appointment of any full-time instructors is a very recent development and has marked a signal educational advance.

### Nursing the Sick

With the development of nursing education which we visualize in the future, and particularly with the growth of University Schools of Nursing, to be discussed in a succeeding paragraph, the field for well-qualified teachers of nursing should prove an increasingly attractive one. We believe we may safely advance as

*Conclusion 2.—That the career open to young women of high capacity in public health nursing or in hospital supervision and nursing education is one of the most attractive fields now open, in its promise of professional success and of rewarding public service; and that every effort should be made to attract such young women into this field.*

We may pass next to the urgent and fundamental problem of providing nursing care for the sick of the community. Here we find far less

unanimity of sentiment in regard either to the quantitative or the qualitative adequacy of nursing service under existing conditions. An appalling shortage of nurses existed during the war; but conditions have materially changed during the past three years. The census reports show an increase in trained registered nurses, male and female, from 82,327 in 1910 to 149,128 in 1920, a truly phenomenal increase of 83 per cent. Some eleven thousand of these are employed as public health nurses and approximately the same number in hospitals and other institutions, leaving over 120,000 for private duty service, of whom, however, many are not in the active practise of their profession. This 1920 figure gives us a ratio of one trained nurse to seven hundred persons for the country as a whole. The majority of trained nurses are concentrated in the larger cities so that the rural districts in many states are wholly lacking in service of this kind. The evidence is, that at present in the cities the supply of trained nurses is adequate to existing demands in normal times. The reason why many persons who need nursing care in hospitals and in the homes of the poor fail to receive it is to be sought in economic factors, rather than in a shortage of nurses.

In regard to the quality of the nursing service available at the present day we find even more radical differences of opinion. Private physicians, frequently express the view that for ordinary nursing, even the graduate of the existing training school is "over-trained," that the service which she renders is too costly, and that a woman with a very brief training in bedside routine would be as satisfactory, or perhaps more satisfactory, than the average registered nurse. As a result of this feeling there have been persistent and vigorous efforts in certain quarters to break down the standards of nursing education which have been laboriously built up during the past twenty years.

Insofar as these efforts would remove the safeguards which guarantee to the patient suffering from acute disease, and to the physician caring for such a patient, the quality of service necessary for safety, we feel that they constitute a real danger to the cause of public health. Nurses, physicians, hospital authorities and legislators, in erecting these safeguards, have been inspired by a just sense of the vital dangers to life which may result from the unskilled nursing of a critical case and of the grave responsibility incurred by both the medical and the nursing professions when

such malpractice occurs. We would therefore record our conviction in regard to this point as:

*Conclusion 3.—That for the care of persons suffering from serious and acute disease the safety of the patient and the responsibility of the medical and nursing professions demand the maintenance of the standards of educational attainment now generally accepted by the best sentiment of both professions and embodied in the legislation of the more progressive states and that any attempt to lower these standards would be fraught with real danger to the public.*

### Subsidiary Nursing Service

When we find that certain private physicians, like the public health administrators, demand nurses of a higher quality than those now in the field, while others desire merely "hands for the physician" with a minimum of education below the present standard, it seems probable that there is reason on both sides and that the apparent conflict is due to a difference in the objectives to be met. For the care of acute and serious illness and for public health work it seems certain that we need high natural qualifications and sound technical education; for the care of mild and chronic and convalescent illness it may well be that a different type of capacity and training may be necessary.

It seems clear to the Committee, however, that, if two types of nursing service are desirable, the distinction should be drawn not on economic grounds but according to the type of illness involved. We are even somewhat doubtful as to the possibility of attaining very substantial economies by the introduction of a subsidiary type of private duty nurse. Our survey of the situation does not indicate that the income of the private duty nurse is at present generally an exorbitant one, when we take into account the amount of unemployment—amounting in a typical group of 118 nurses to a week each month during the busy winter season. If this factor be allowed for, the margin between the average annual income of the private duty nurse and that of the domestic servant is not so great as to permit of the existence of an intermediate grade on a salary level very much below that of the present Registered Nurse. The solution of the economic problem which confronts the family of low income must probably be sought along the line of cost distribution through some form of community organization or along the line

of group insurance such as that now being experimentally tested in New York City.

In any event, a pneumonia case, a diphtheria case, a grave cardiac case will require the highest grade of nursing obtainable whether it occurs in a palace or a hovel. It is the mild and chronic and convalescent case which offers a field for the partially trained worker, and the exact extent of this field has never yet been fully surveyed. In our own study we have secured careful estimates from 118 graduate nurses which indicate that during a period of three months one quarter of their time was spent on cases which could have been cared for by an attendant of the partially trained type. A somewhat similar estimate was obtained from forty-eight practising physicians, twenty-one believing that trained nurses were unnecessarily employed for less than a quarter of their cases, seventeen placing the figures between half and three-quarters and ten at over three-quarters.

In considering the problem of subsidiary nursing service it must be remembered that we are dealing with no new development. Of the three hundred thousand male and female nurses in the United States in 1920, slightly more than half were of grades below the standard of the graduate nurse. The "practical nurse" the "trained attendant," is an existing fact; and in the opinion of a large group of the medical profession who utilize her services she fills a real place in the complex problem of caring for the sick. If we include with the trained and registered nurses (149,128) the student nurses in hospitals (54,953) and to these add the number of attendants and practical nurses, (151,996) as constituting the entire body of persons occupied in caring for the sick we have altogether one nurse, trained or untrained, to every 294 well persons. This would seem to give an adequate supply if numbers alone are considered, provided a proper distribution could be secured.

On the other hand the dangers in the existence of a loosely-defined and unregulated group of partially trained workers, in the same field with a more highly educated type, constitutes a real and a serious complication. The nursing profession has discharged a fundamental duty to the public in stimulating the development of registration laws which define and limit the practice of that profession and protect the community against fraud and exploitation by

those who collect fees and assume responsibilities to which their qualifications do not entitle them. In addition to the registration of the trained nurse it is essential that the lower grade of nursing service should also be defined and registered; and the states of New York, Missouri, California, Michigan, and Maryland have taken definite steps in enacting legislation toward this end. The name to be selected for the subsidiary group is a difficult problem. As is often the case the root of disagreement lies largely in nomenclature. The title "attendant," embodied in three of the laws mentioned above, is distasteful to those who bear it and tends to discourage the enlistment of those who may desire to enter this field. On the other hand the term "practical nurse" assumes a most unfortunate antithesis between education and practice; and the splendid professional and public service rendered by "the nurse" in war and in peace, entitles her to the protection of her existing professional status. We are inclined to believe that the term "nursing aide" or "nursing attendant" best meets the need for clear differentiation, while providing the subsidiary worker with a suitable name.

With two distinct grades of service available, the individual physician would be responsible for the choice of a trained nurse or a nursing attendant or nursing aide in a given instance. The public can only be safeguarded in these matters by state legislation providing for licensing of nursing registries and requiring explicit statement as to the license qualifications of each nurse or nursing aide furnished. We believe that by this means the maximum increase of nursing service possible under existing economic conditions could be attained; and we would therefore recommend as

*Conclusion 4.—That steps should be taken through state legislation for the definition and licensure of a subsidiary grade of nursing service, the subsidiary type of worker to serve under practising physicians in the care of mild and chronic illness and convalescence and possibly to assist under the direction of the trained nurse in certain phases of hospital and visiting nursing.*

Our survey of the actual field of nursing service has thus led us to the conclusion that the good of the community demands (a) the recruiting for public health nursing, hospital nursing, and the care of the acutely ill of a larger number of young women and the provision for such women of

a sound and effective education; and (b) the development and standardization of a subsidiary nursing service of a different grade for the care of mild and chronic disease. We may next pass to the second part of our problem—a consideration of existing educational facilities for the training of the two types of workers indicated as desirable.

So far as the trained nurse is concerned, whether she is to function in private duty, in public health, or in institutional service, it is clear that her basic professional education must be acquired in the hospital training school. We have therefore devoted a major part of the present investigation to a somewhat detailed study of existing conditions and future possibilities in hospital training.

### Hospital Training School

The development of the hospital training school for nurses constitutes a unique chapter in the history of education. In almost all fields of professional life education has begun on a basis of apprentice training. The first law schools and the first medical schools were the outgrowth of the lawyer's and the physician's office. In nearly all other fields than that of nursing, however, even in such relatively new professions as journalism and business and advertising, education has outgrown the apprentice stage and leadership has passed into the hands of independent institutions, organized and endowed for a specifically educational purpose. The training of nurses, on the other hand, is still in the main, actually if not technically, directed by organizations created and maintained for the care of disease, rather than for professional education.

The progress which has been accomplished in nursing education, under such anomalous conditions, is such as to reflect high credit upon both hospital administrators and the leaders of the nursing profession. The hospitals have in many instances been inspired by a broad and constructive vision of training school possibilities; while the devotion with which nursing directors have labored for high standards, often against almost insuperable obstacles, calls for the warmest admiration. Yet the conflict of interests between a policy of hospital administration, which properly aims to care for the sick at a minimum cost, and a policy of nursing education which with equal propriety aims to concentrate a maximum of rewarding training into a minimum time, is a real and vital one.

The fact that a field so tempting as that of modern nursing, with its remarkable possibilities of service in public health, in institutional management and in teaching, fails to attract students in the number and of the quality we should desire, strongly suggests that there is some shortcoming in the established avenues of approach to the nursing profession. The hospitals themselves, depending as they do so largely upon student nurses for their routine operation, have in past years found themselves seriously handicapped by the small number of applicants, and many a superintendent will testify to the fact that the difficulty of securing a high quality of nursing is one of the gravest which he has to meet. The phenomenally rapid growth in the number of hospitals has created within a brief period a demand for a large number of students and the requirements for admission have therefore been kept at a very low level, thus resulting in a reduction in the proportion of well-educated applicants. For the good of the hospital, as well as for that of the nursing profession and of the public at large, a careful and dispassionate appraisal of the adequacy of the present day training school would seem to be urgently desirable.

### Training Schools Studied

An extensive survey of the vast field of hospital training schools (there are over 1,800 such schools in the United States) was obviously beyond the possible resources of our committee. It was therefore decided to select a small group of schools, of reasonably typical character, for intensive study. Twenty-three such schools were finally chosen, representing large and small, public and private, general and special hospitals, in various sections of the United States. These schools were undoubtedly well above the median grade and their average may, we believe, be taken as fairly representative of the best current practice in nursing education. Each school was studied in detail by two types of investigators, one a practical expert in nursing education and the other an experienced educator from outside the nursing field. By this means we aimed, on the one hand to secure competent criticism of nursing procedures, and on the other a broad viewpoint of general educational standards. The detailed results of this investigation, as presented in Miss Goldmark's report will, we believe, prove highly enlightening to the student of this problem.

The training of the nurse involves

a certain basic knowledge of the fundamental chemical and biological sciences, theoretical instruction in the principles of nursing and above all, supervised practical training in actual nursing procedures. In all three phases of this work Miss Goldmark's report reveals conspicuous successes and equally conspicuous failures; and the remarkable thing is that successes and failures so often appear side by side in the same institution.

Thus, we may find in a training school with a good ward service that the fundamental science courses fail because of wholly inadequate laboratory equipment. In another school, the theoretical instructor may show a hopeless lack of teaching ability (as in the case of class presentation which consisted in the dictation of questions and answers from a prehistoric notebook); or she may be so handicapped by other duties as to leave no time for the proper conduct of her classes. Lectures by physicians may be informative and inspiring in one department of a hospital, irregular in delivery, careless, and dull in content in another. Ward assignments are in many cases largely dictated by the need for hospital service rather than by the educational requirements of the students. This is clearly evidenced by the astonishing irregularity of the time spent on different services by individual students and by the marked deviation between all the time assignments actually performed and those scheduled in the official program of the course. Thus in one school where seven and a half months were assigned to surgical service the members of a single class had actually worked on this service for from seven to thirteen and three-quarter months. Of the twenty-three schools surveyed by us one made no adequate provision for obstetrical service, while five gave no training in pediatrics, seven, no experience in communicable disease, and eighteen, none in mental disease. In view of the difficulties in making affiliations in some of these subjects, notably in communicable and mental disease, some of these omissions are scarcely to be wondered at.

The supervision of work on the wards was in certain instances notably inadequate. In only a few brilliantly exceptional cases was the ward work purposefully correlated with theoretical instruction. The lack of an intelligently planned progressive training was obvious in a large number of the hospitals studied, first year students often being found in positions of responsibility for which they were wholly unprepared, while seniors

in another ward were repeating an educationally idle and profitless routine. Most striking of all, was the factor of time wasted in procedures, essential to the conduct of the hospital, but of no educational value to the student concerned. Hours and days spent in performing the work of a ward maid, in putting away linen, in sterilizing apparatus, in mending rubber gloves, in running errands, long after any important technique involved had become second nature, accounted in one typical hospital where this problem was specially studied for a clear wastage of between one-fourth and one-fifth of the student's working day.

The total amount of time assigned to ward service under the conditions which obtain in many hospitals is, in itself, a fairly complete obstacle to educational achievement. Our selected group of hospitals, surely in this respect far above the general average, shows a median day of 8.5 hours on ward duty alone, and unproductive night duty is the rule rather than the exception. Crowded and unattractive living conditions tend, in certain hospitals, to impair the morale of the student body and an atmosphere of autocratic discipline frequently prevents the development of a psychological atmosphere favorable to effective cooperative effort.

The foregoing paragraphs present, we are aware, a somewhat gloomy picture. In presenting them, we would emphasize two points which are of major importance. In the first place, such shortcomings as have been pointed out are not fairly chargeable to deliberate neglect on the part of hospital authorities or nursing superintendents. In so far as they exist, they are due to the inherent difficulty of adjusting the conflicting claims of hospital management and nursing education, under a system in which nursing education is provided with no independent financial endowments for its specific ends. The difficulties involved in the task of resolving this conflict are perhaps illustrated by the fact that out of 144 registered training schools in New York State, 60 changed superintendents during a single recent year.

In the second place it is encouraging to note, by reference to Miss Goldmark's report, that every one of the shortcomings in hospital training discussed above has been corrected, with substantially complete success, in one or more of the training schools studied by our investigators. The difficulties are not insuperable. Each of them has been overcome in some

schools and most of them in some of the best schools. Training schools exist today in which the student receives a sound and an inspiring education, with a minimum of sacrifice to the exigencies of hospital administration. Yet such schools are still the exception; and we are convinced that the progress we desire can come only through a frank facing of the truth. The following statement is, we believe, thoroughly justified by such facts as we have been able to obtain:

*Conclusion 5.—That, while training schools for nurses have made remarkable progress, and while the best schools of today in many respects reach a high level of educational attainment, the average hospital training school is not organized on such a basis as to conform to the standards accepted in other educational fields; that the instruction in such schools is frequently casual and uncorrelated; that the educational needs and the health and strength of students are frequently sacrificed to practical hospital exigencies; that such shortcomings are primarily due to the lack of independent endowments for nursing education; that existing educational facilities are on the whole in the majority of schools inadequate for the preparation of the high grade of nurses required for the care of serious illness, and for service in the fields of public health nursing and nursing education, and that one of the chief reasons for the lack of sufficient recruits, of a high type, to meet such needs lies precisely in the fact that the average hospital training school does not offer a sufficiently attractive avenue of entrance to this field.*

#### Recommendations Made

Recommendations for the improvement of the hospital training school are therefore made on the basis of these conditions. Miss Goldmark's study has not stopped short with a revelation of the defects which are commonly found in the conduct of nursing education. It makes clear that only the coordination and standardization of the best existing practice is necessary in order to place nursing education on the plane where it belongs.

In the first place we believe that a training school which aims to educate nurses capable of caring for acute disease or of going on into public health nursing or supervisory and teaching positions must require for entrance the completion of a High School course or its equivalent. Nearly one-third of all the training

schools in the United States now make this requirement and with 150,000 girls graduating from High Schools every year it should be possible for well-organized courses to attract an ample number of candidates.

The course should begin with a preliminary term of four months' training in the basic sciences and in elementary nursing procedures with appropriate ward practice but without regular service, as outlined in Miss Goldmark's report. The necessary teaching personnel and laboratory equipment for the former may in many instances be secured by the smaller hospitals through the establishment of a central training course or by cooperation with High Schools, Normal Schools, or Junior Colleges.

There should then follow a period of twenty-four months (including two months for vacation) devoted to a carefully graded and progressive course in the theory and practice of nursing, with lectures and ward practice so correlated as to facilitate intelligent case study and with the elimination of routine duties of no educational value. Hospital and dispensary services in medicine, surgery, pediatrics, obstetrics, communicable diseases and mental diseases should be provided through appropriate affiliation. Teachers and equipment should be of such a grade as would be acceptable in a reputable college or normal school.

We regard it as fundamental that the working day for the student nurse, including ward work and classroom periods, should not exceed eight hours. The working week should not exceed forty-eight hours and preferably forty-four hours. Training School experience, as well as a comparison with that accumulated in other educational fields, makes it clear that a longer period of scheduled work for the student is incompatible, either with educational attainment or with the maintenance of health.

By such an organization of the course of study, and particularly by the elimination of unrewarding routine service, we are convinced that the period of training may be safely shortened from the present standard of three years to twenty-eight months. Such a saving would mean an increase of over 20 per cent in the potential output of the training school through the saving of time alone. The shortening of the course would, in itself, prove an attraction to the prospective student; but the main consideration to be kept in view is that the shorter course projected would not imply a lowering but a raising of educational

standards. Miss Goldmark's analysis of the situation makes it clear that the intensively planned course of 28 months would involve no substantial sacrifice in a single service as compared with the actual median practice of the present day and would supply other services now almost universally neglected. It is the experience in every other field of education that the way to attract students is to raise standards, not to lower them. In medicine, in law, in engineering, in teaching, the schools which raise requirements are the ones from which students must be turned away; and even in nursing the success of the better schools furnishes convincing testimony to the same basic principle. It is the higher standing of the course here outlined quite as much as its lessened length which we are confident would insure an increase in the number of students, as well as an improvement in their quality.

#### Post-Graduate Education

There are, we believe, two fundamental essentials to the success of a training school planned on the suggested lines. It must first of all be directed by a board or a committee, organized more or less independently for the primary purposes of education. The interests of hospital management and of educational policy must necessarily at times conflict and unless the educational viewpoint is competently represented the training school will infallibly suffer in the end. In the second place, it is fundamental to the success of nursing education that adequate funds should be available for the educational expenses of the school itself, and for the replacement of student nurses by graduate nurses and hospital help in the execution of routine duties of a non-educational character. A satisfactory relationship between school and hospital demands careful cost-accounting and a clear analysis of the money value of services rendered by the school to the pupil and the hospital, by the pupil to the hospital, and by the hospital to the pupil and the school. The cost of adequate education must in any case be a paramount consideration, to which we shall return in a succeeding paragraph. Assuming its essential importance, the following conclusion seems to be justified:

*Conclusion 6.—That, with the necessary financial support, and under a separate board or training-school committee, organized primarily for educational purposes, it is possible with completion of a high school course or its equivalent as a prerequisite, to re-*

*duce the fundamental period of hospital training to 28 months and at the same time, by eliminating unessential, non-educational routine, and adopting the principles laid down in Miss Goldmark's report to organize the course along intensive and coordinated lines with such modifications as may be necessary for practical application; and that courses of this standard would be reasonably certain to attract students of high quality in increasing numbers.*

The course of twenty-eight months discussed above would furnish the complete education for a student desiring to practise as a bedside nurse in private duty or in hospitals and other institutions; and its completion should entitle her to the Diploma in Nursing and to state registration. For the nurse who desires to specialize along either of the more advanced lines, of public health nursing, or hospital supervision and nursing education, a further period of post-graduate training is obviously desirable.

Teachers College of Columbia University has played the part of pioneer in preparing graduate nurses for hospital supervision and nursing education and certain of the newer University Schools of Nursing are already offering attractive courses along the same line. The development of graduate courses in public health nursing has made even more notable progress. The first organized course of this type was offered in Boston in 1906 and by 1920 there were twenty such courses in operation, under the auspices of Universities, Public Health Nursing Associations or Schools of Social Work.

The activities of sixteen of these schools of public health nursing have been studied in the course of our investigation and the results achieved in this new field are in general deserving of high praise. The course is apparently in process of standardization at a length of about eight months, four devoted to theoretical instruction in public health, public health nursing, educational psychology and social problems, and four to supervised field work with a public health nursing organization. The courses at present offered are in many instances tentative and lacking in assured financial status. With the development of the University School of Nursing, (to be discussed in succeeding paragraphs) they may be expected to fall within its sphere of influence and to develop an increasing stability and usefulness.

*Conclusion 7.—Superintendents, supervisors, instructors, and public*

health nurses should in all cases receive special additional training beyond the basic nursing course.

For advanced training, the development of the University School of Nursing has been perhaps the most notable feature in the progress of nursing education during the past ten years. As long ago as 1899 Teachers College of Columbia University admitted properly qualified nurses to its junior class, thus giving two years of college credit for the three years of nursing training. Since 1916, no less than thirteen different colleges and universities have provided combined courses, through which students may acquire both a nurse's training and a college degree.

### University School of Nursing

The combined course, in such schools for example, involves two years of ordinary college work including besides work of a liberal nature certain of the fundamental sciences basic in nursing education. Then follow two years of intensive training in the hospital and finally, a fifth year of post-graduate education in one of the higher specialties of nursing, public health, institutional supervision, or nursing education. At the close of training, the student receives a diploma in nursing and the bachelor's degree in nursing or in science.

This type of School of Nursing should in the judgment of the Committee be a separate and independent department of the University, cognate in rank and organization with the School of Medicine or the School of Law. It should have direct responsibility for all instruction given during the years of hospital training and the post-graduate nursing year.

A definite affiliation with one or more hospitals must in any case be established, along the line of those agreements now in force between medical schools and hospitals. The school supplies student nursing service and assumes a definite responsibility for a larger or smaller share of ward supervision and perhaps of graduate service. The hospital, on the other hand, provides maintenance for the nursing staff and conforms to the standards held by the University to be essential for the realization of its educational ideals. A University Hospital will of course offer the most promising field for a University School of Nursing; but in default of such an institution there seems no reason why a University School should not establish satisfactory working agreements with various adjacent hospitals, provided only that the maintenance of adequate

standards in the practice field remains in its own hands.

If its present practical function be clearly understood the University School of Nursing possesses unique advantages in respect to both of the essentials for success in nursing education, to which reference has been made in a preceding paragraph. It possesses the power of independent educational leadership and is grounded on the solid foundations of educational ideals, to a degree which a training-school committee, ultimately responsible to a board of hospital trustees, can seldom hope to realize; and it is likely to obtain financial resources of a more nearly adequate extent. Furthermore, through its university contacts the University School of Nursing has unique opportunities to attract students of the type so greatly needed for the fulfilment of the higher tasks in the nursing of the future.

It should be made quite clear that the Committee does not recommend that nursing schools in general should work toward the establishment of courses of a character that a University would accept for a degree. We realize that the numerical proportion of the nursing profession to be contributed by the University School will perhaps always be a relatively small one. Yet we believe that the importance of this portion of the educational structure would be difficult to overestimate. The value that we see at present in the University Schools is that they will furnish a body of leaders who have the fundamental training essential in administrators, teachers, and the like. One of the greatest, if not the greatest of the reasons for the imperfections in the present training of private duty nurses is that great numbers of schools have developed without any coincident development of adequate numbers of persons properly trained to guide the pupils during their course. Unless well taught they cannot be well trained. The University School of Nursing should be the keystone of the entire arch. It will not only train leaders and develop and standardize procedures for all other schools. It will, by its permeating influence, give inspiration and balance to the movement as a whole and gradually but steadily improve the efficiency of every institution for the training of nurses of whatever type. We would therefore urge as

*Conclusion 8.—That the development and strengthening of university schools of nursing of a high grade for the training of leaders is of funda-*

*mental importance in the furtherance of nursing education.*

We have pointed out in a preceding section of this report that there appears to be a real place for nursing service of a subsidiary type, to be used in the institution and in the home, for the routine care of patients suffering from disease of a mild or chronic type or in convalescence. We have also pointed out that this subsidiary service is an existing fact, whether we like it or not.

Existing facilities for the training of the subsidiary worker are today of the most limited type. It is obvious that courses in home nursing of a few weeks duration, such as those conducted under the auspices of the American Red Cross, while most useful in disseminating the sort of knowledge which all girls and women should possess, in no way suffice as preparation for the practice of a profession. When they are advertised as adequate for this latter end, such courses may do far more harm than good—as evidenced by the fact that "graduates" of such courses after forty-eight hours of instruction have practiced as qualified nurses and received \$5 a day for their services.

### Training of Subsidiary Workers

Courses for the training of nursing aides offered by the Household Nursing Association of Boston and by local Young Women's Christian Associations in various parts of the country and those stimulated by the Bureau for the Home Care of the Sick under the Thomas Thompson Trust are on a wholly different basis. The number of graduates from such courses is, however, small and their control after graduation loose and unsatisfactory. Since the existence of the subsidiary nursing group is a concrete fact, and in view of the valuable results to be derived from the service of this group in a definitely restricted field, it seems obvious that specific provision should be made for the training of workers of this type.

The field for the training of nursing aides would seem to be an ample one. The special hospital, not served by affiliation with a school of nursing, and the small general hospital whose facilities are inadequate for the maintenance of a nursing school of standard grade might be considered as training grounds. In the large general hospital whose opportunities are not fully utilized by student nurses there is no valid objection to the training of the subsidiary group, provided that it is conducted in separate and distinct wards so that the sac-

rifice of the interests of either of the two groups of pupils may be avoided. The requirements for entrance should be a grammar school course or its equivalent and the period of training eight or nine months. Suggestions of great value in regard to the safeguarding of such a course for "attendants" will be found in a recent report issued by the Board of Regents of the University of the State of New York.

It is essential in providing for this new type of education that hospital patients should be protected from malpractice and students from exploitation by an adequate graduate nursing service for the care of acute illness and for supervision of the students. Again, therefore, we must assume a reasonable financial support before this, or any other, educational enterprise can be honestly undertaken. Furthermore, we believe that a useful development in the training of nursing aides can only be expected when the standards of the schools for such aides and their activities after graduation are controlled by a properly safeguarded system of state legislation, such as now exists in Missouri.\* With these assumptions we would recommend as

*Conclusion 9.—That when the licensure of a subsidiary grade of nursing service is provided for, the establishment of training courses in preparation for such service is highly desirable; that such courses should be conducted in special hospitals, in small unaffiliated general hospitals or in separate sections of hospitals where nurses are also trained; provided the standards of such schools be approved by the same educational board which governs nursing training schools; and that the course should be of eight or nine months duration.*

### The Financial Problem

We believe that the educational plan which has been outlined above is, according to existing information, necessary and sufficient for the solution of the problems involved in securing an adequate nursing service of all essential types. The school for nursing aides would provide the subsidiary worker needed for the care of the mild and chronic and convalescent case. The hospital training school, with adequate funds and an independent educational organization, would attract more candidates and better candidates and would prepare them ade-

quately for the nursing of acute disease. The University School of Nursing would prepare the leaders in public health nursing, in hospital supervision and nursing education and would inspire and standardize the entire movement. Progress must be made gradually, of course, building up for the future, step by step, upon the basis of existing facilities.

It is clear, however, that the attainment of these ends requires financial support, and requires it at all points along the line. The training of nursing aides will cost money; the training of nurses will cost more money; the University School will require endowment on a reasonably generous scale. The hospital, in its operation of the training school has for generations been trying to make bricks without straw, in the upbuilding of an educational system on an apprentice basis and without independent educational resources. It has made every possible effort—except the effort to secure educational endowment; it is time that the hospital should be relieved from the dilemma of exploiting student nurses on the one hand, or of diverting funds given for the care of the sick on the other, by the provision of endowments specifically devoted to the purposes of education.

We are well aware that many of those who have taken counsel with us in regard to this matter have cherished the hope that the Committee would find some magic pathway out of the maze of nursing education; but such hopes are vain. There is no short cut to the end which we all have in view. The establishment of a sound educational policy is the one essential to attracting students in quantity and of quality; and a sound educational policy requires specific financial support. If the community needs and desires the service of competent nurses for the care of the sick and the prosecution of the campaign of public health, it must pay for their education, as it pays for every other conceivable kind of education—either through taxes or through voluntary contributions or through the generosity of its great philanthropic foundations. No broadly conceived and systematic effort to obtain such financial support for nursing education has ever yet been made; when it is made we are convinced that it will not fail. In institutions where nursing education has been even partially endowed, as in the first school of nursing at St. Thomas' Hospital, London, and the Department of Nursing and Health at

Teachers' College, New York, substantial achievements in the better education of nurses have been rendered possible.

It is obvious that the plan recommended for improvement of the education of nurses cannot be adequately put into effect in any hospital training school without additional funds for this purpose. The strategic position which the University Schools of Nursing will occupy in regard to the whole movement indicates their development as of special importance. An adequate endowment for a group of such University schools would establish centers of influence which could safely be trusted to exert a profound influence upon nursing education. We, therefore, urge as the final conclusion from our study of this problem:

*Conclusion 10.—That the development of nursing service adequate for the care of the sick and for the conduct of the modern public health campaign demands as an absolute prerequisite the securing of funds for the endowment of nursing education of all types; and that it is of primary importance, in this connection, to provide reasonably generous endowment for University Schools of Nursing.*

### Vocational Guidance in Philadelphia

A report of the White-Williams Foundation, Philadelphia, covering the work of the five years since the organization entered upon its present program of vocational guidance has recently been published. The School Counseling department has had counselors in 14 different schools since the beginning of this work, and has studied in all 3,812 children. Scholarships have been provided for 142 pupils, 69 of them during 1921. Nearly 90 teachers and principals applied for the 25 scholarships offered by the Foundation in the fall of 1921 for the special course in social work in the schools given at the Pennsylvania School for Social Service, and so many inquiries came from others that two other courses have been organized for the second semester.

The appointment of Dr. Ethel M. Watters of San Francisco as consultant in the administration of the Shepard-Towner Maternity Act has been announced by the U. S. Department of Labor through the Children's Bureau. Dr. Watters has been since 1919 Director of Child Hygiene in the California State Board of Health.

\*The Missouri act is unusually effective in providing that "no person shall practice as a nurse for hire or engage in the care of the sick as an attendant for hire unless licensed by the Board as hereinafter provided."

## Digest of Sanitary and Hygienic Advance

THE activities of the laboratory ever have a direct bearing upon the practical work of the health official, but never before in the history of health work have so many problems of far reaching significance occupied investigators as at the present time. The field is wide. Each of the sciences must contribute its quota to the working knowledge of the public health worker.

### Pulverized Small Pox Vaccine for Tropical Use

One of the greatest deterrents to successful vaccination in the tropics is the difficulty of maintaining the potency of the vaccine in situations remote from ice. Various expedients have been resorted to, of which the best has been the thermos bottle. The method is to fill the bottle about half full of finely cracked ice, then a layer of capillary tubes of vaccine matter, tied in bundles of forty each, then a final layer of cracked ice. When vaccinations are to be performed, the metal cap of the bottle is almost filled with ice water containing a few pieces of ice and a bundle of vaccine tubes, which are removed from the ice water one by one as needed and only immediately before application to the scarified area. Even with the greatest care, it frequently happens that the number of positive results is not greater than 10 per cent or 15 per cent. The Director of Health of the Philippine Islands, Dr. Vicente de Jesús, in his report for the calendar year 1920 expresses the belief that these difficulties have been overcome by the use of the pulverized smallpox vaccine prepared by the Philippine Bureau of Science. Since this statement grows out of the observations of nearly fourteen million persons since 1918, it should carry great weight. The dried vaccine is put in one rubber-stoppered amber glass vial and the glycerin for making the suspension in another, fifty units in each vial. The vaccine must be kept in a cool, dark place and must not be exposed to direct sunlight or artificial heat if its potency is to be maintained. To use, the stoppers are drawn from both vials; the glycerin is poured into the vial containing the pulverized vaccine; that vial is re-stoppered and shaken until the powder is completely emulsified. Vaccinations should follow immediately. It is claimed that by this method, positive results are

obtained in 70 per cent of vaccinations.

TUBERCULOSIS is a dirge whose notes arise from the cradle.

### The Prophylaxis of Syphilis

Levadaditi and Navarro-Martin presented to the French Academy of Sciences, at its session of March 21, 1922, (*Par. Med.* XII, No. 14, p. 304, Ap. 8-22) a note on the prevention and cure of syphilis by the use of acetyl derivative of oxyaminophenylarsinique, which is a soda salt. This method of prophylaxis depends upon the employment of an efficient spirillicide which, from a practical point of view, is more simple of application than by the use locally of ointments or preventive injections. The attempt to achieve results by the administration of bismuth salts by mouth proved negative or mediocre. The authors tested this method with the new salt of arsenic mentioned above. The drug administered by the buccal route produced a rapid and definite cure of the lesions of syphilis in rabbits and monkeys, the Trypanosomes disappearing on the second or third day and not returning. Experiments were then made on man, sixteen grams being administered to one patient and fourteen grams to another, at the rate of from one to two grams daily, taken in a single dose, fasting. The Trypanosomes disappeared rapidly from the lesions. After a number of confirmatory experiments, a volunteer, a young man of twenty-five years, allowed himself to be inoculated with the virus of syphilis into scarifications in each arm. At the same time a macacus monkey was inoculated with some of the same material as a control. Two hours and sixteen hours respectively after the inoculation, the young man was given two grams of the new arsenic salt by mouth but the monkey was given none of the drug. Ten days later, the monkey presented typical syphilitic lesions. The young man was observed for

forty-three days but developed no local reaction or general signs of syphilis and his Bordet-Wassermann reaction remained continuously negative. The authors conclude that this new salt is a drug which when administered by mouth prevents infection with syphilis and produces rapid cicatrization of the manifestations of syphilis in man and animals. It will of course require time to decide if this new therapeutic agent will always prevent the disease and whether its cures are definite and permanent.

### Method of Fly-Catching

The Health Department of the city of Panama, R.P., for more than two years has been making its own sticky fly solution. This is made by heating together five quarts of castor oil with twenty pounds of clear resin, with stirring, until a clear solution is formed. This may be spread on sheets of paper or long spirals of paper. Neither of these methods is neat. The pieces of paper blow about and other things besides flies get stuck on them. Furthermore, it is not easy to place them where the fly most commonly alights, that is on projections nearer the ceiling. It was found that wires coated with the sticky solution make good fly traps. For this purpose baling wire is bound into hanks the upper end of which is bent into a hook. Baling wire is used because it is a suitable size and discarded pieces may almost always be secured free around any stable using baled hay. As soon as the hank of wire has become covered with adherent flies, it is cleaned by washing with boiling water and lye, after which it is re-dipped. For catching flies on tables, it was found that a spiral spring, such as is commonly used in automobile or other upholstery, serves admirably when dipped in this solution. The base of the spring is fixed to a square piece of board or metal. Such springs may be secured free from discarded upholstery. The method is simple, inexpensive and efficacious (Fig. 1).

Fig. 1. Simple and practical method of fly catching.

Hours of Sleep Requisite for Children

Anyone who has inspected very many school children must have been struck with the fact that while many were alert and wide-awake others were heavy eyed and dopey. Almost uniformly, though, the children claimed to have gone to bed early. As a matter of fact, however, it is entirely probable that the average child does not get enough sleep and as the age of the child progresses, the loss of sleep increases in proportion. Authorities vary considerably in their estimates of the amount of sleep which should be taken by the average healthy child of a given age. Certainly if the table given by Dr. Clement Dukes in *School Hygiene*, November, 1921, be taken as a standard, it is easy to believe that most children are underslept.

Age	Hours	Age	Hours
At birth	23	8 years	12
1 year	20	9 years	11½
2 years	18	10 years	11
3 years	16	13 years	11
4 years	15	15 years	10½
5 years	14	17 years	10½
6 years	13	19 years	9½
7 years	12½	All other ages	9

Gross (*Lancet*, CCII, 5148, Ap. 29-22, 836 et seq) who has made a careful study of the sleep of elementary school children arrives at the conclusion that only a very small percentage of elementary school children attain the hours of sleep recommended by Dr. Dukes, the great bulk falling considerably below and a considerable number far below his standard. He states that the percentage of children showing fatigue signs and also the percentage which have to be wakened in the morning increases with the age of the children because of the gradual and premature freeing the child from parental control. The ideal corrective procedure seems to be the teaching of parents that children require very considerable amounts of sleep in order to develop properly.

Advice for the Research Worker

The late Sir Patrick Manson's advice to those entering the field of research: "Never refuse to see what you do not want to see, or which might go against your most cherished hypotheses, or against the views of authorities. These are just the clues to follow up, as is always, and emphatically so, the thing you have never seen or heard of before. The thing you cannot get a pigeon-hole for is the finger-point showing the way to discovery." An illuminated copy of this should hang on the wall of every research laboratory.

Chloropicrin as Ship Fumigant

Sulphur dioxide is the aeon-old standby in ship fumigation. It is a fairly good agent of deratization; accidents to human beings very seldom follow its use; it is relatively cheap; it requires very little apparatus to use; highly skilled labor is not absolutely necessary in its application. On the other hand, its diffusibility is not good; its weight sometimes makes post fumigation aëration somewhat slow; it is destructive to colors, and tarnishes, or even corrodes certain metals.

Carbon monoxide is of considerable value; it is fairly efficacious for killing small mammals; it is fairly cheap; it is not destructive; there is no danger from fire during its use, as with sulphur dioxide; it is light and aëration is easy following its use. A special apparatus and skilled operatives are required for its use; its diffusibility is not uniform and is uncertain; in the presence of a humid atmosphere it is apt to cause sweating of painted surfaces; it is odorless, tasteless, non-irritant and invisible and has therefore the great hazard that someone may walk into it and be killed.

Hydrocyanic acid gas is an extremely valuable fumigant; it is highly lethal for mammals, many insects and all birds; it is highly diffusible, relatively cheap, and not destructive. Skilled and dependable labor is required for its use; aëration must be perfect before the fumigated compartments may be entered. It is a useful but highly dangerous weapon in the armentarium of the sanitarian.

An attempt was made by Seguy F. (*Arch. de Med. et de Pharm.* Nav. 1921, III, No. 6, p. 509 et seq.) to utilize chloropicrin in the proportion of 5 cc. per cubic meter as a deratizing fumigant for ships. The chemical formula of chloropicrin is  $CCl_2NO_2$  and is made by the action of calcium hypochlorite on calcium pierate. It boils at 111.9° C., freezes at -602° C. and has a density of 1.648 at 25° C. It is an intense lachrymant. For a ship of four thousand cubic meters capacity—about 1,500 registry tons—twenty liters at a total cost of 280 francs—about \$50 gold—were required. The agent killed all rats and bugs, but twenty-four hours aëration was necessary. The difficulty of removal of the gas by ordinary ventilation methods, interposes an almost insuperable obstacle by reason of the time element involved. This gas is relatively safe, however, because no one will walk very far into it.

Production of Chenopodium Oil in the Dutch East Indies

The annual report of the medical services in the Dutch East Indies (excerpted by the Sanitary Supplement of the *Tropical Diseases Bulletin* of March 30, 1922), notes the encouragement of the cultivation of *Chenopodium ambrosoides* by private agriculturalists, the chenopodium shrub being planted in various rubber gardens between the hevea. As a result, an oil of efficacy equal to that of the imported article is produced and sold 10 per cent below the usual market price. This same thing might easily be done on the banana, coffee, and cacao plantations of Central and South America.

Squill Effective as a Rat Poison

Many observers abroad are of the opinion that fluid extract of squills is a most efficient rat poison. It is claimed that it has thrice the toxic effect of barium carbonate and is relatively harmless to animals and birds. It is cheap and, since it creates great thirst, the poisoned rodents die in the open. It is prepared by macerating freshly purchased bulbs of *Urginea maritima* with alcohol 1:5 for six days and then expressed through a cloth. The baits are prepared by soaking small pieces of bread in the fluid extract. Poisoned animals are dead by the second day.

Rabies Decreasing in France

Rabies, which increased very appreciably in France during the War, is reported to be on the decrease, in spite of the fact that new foci occasionally develop. The control of the disease has resulted from the usual measures for the control of dogs, particularly stray dogs. The continuance of the disease is believed to be due to the failure on the part of owners of dogs to report the infection in their animals (*Gaz. d. Hôp.* No. 20, Mar. 11-22, p 306).

Building Malaria Out of Existence

In breaking the chain of continuance in malaria, it is important to prevent the creation of human chronic carriers. To this end it has been suggested (*van Lankhuijzen, Meded. v. d. Burgerlijk Geneesk. Dienst in Nederl. Indae, 1920, pt. 10, pp 50-75- excerpted Sanit. Sup. Trop. Dis. Bul., Mar. 30-22, pp 1-3*) that all houses be registered and numbered and that the building of houses for human occupancy without license be prohibited, applicant to be advised regarding site and methods of mosquito exclusion.

care of mild and chronic illness and of convalescence; and that courses of nine months duration should be offered for the preparation of workers of this type. In the second place it is recommended that the basic course for the trained nurse, who is to function in the care of the acutely ill, should be shortened from three years to two years and four months, but with standards as to the solidarity and intensiveness of training which will mean no lowering but rather raising of actual educational achievement. Finally, for public health nursing and hospital supervision and nursing education a graduate course of at least eight months more will be required.

Perhaps the most important point emphasized by the Committee is the need for endowment for nursing education. It is frankly recognized that the vast majority of nurses' training schools are today quite inadequate for the fulfilment of the task which is placed upon them and this must necessarily be the case so long as nursing education is carried on without endowments of its own and as an adjunct to hospital administration. Independent educational management and specific educational endowment are essential if the pupils of training schools are to receive an intensive and purposeful education freed from the burden of repetitive and unrewarding routine. There is probably no field of community activity in which educational endowments are so much needed as in connection with nursing education and it is well that this problem has been so clearly and emphatically stated by a group of men and women of authoritative standing.

It is believed by the Committee that the highest type of public health nursing is that in which bedside care and instructive work is combined and for this field women of high natural qualifications are greatly needed. Hospital teaching and supervision is another career of the highest attractiveness for young women of vision and ability and it may be hoped that if the necessary funds are obtained and the nurses' training school is placed on an adequate basis young women in increasing numbers and of increasingly high calibre will be drawn into a profession which today offers unique opportunities for constructive social service.

## Chicago Community Trust Makes Study of Prenatal Care

THE Chicago Community Trust has presented to the public a valuable study on "Prenatal Care in Chicago." The Chicago Community Trust is a foundation whose business is to receive funds in trust for the benefit of the community and to aid those who are seeking an outlet for benevolences. It is interested, therefore, in a

## A Constructive Policy of Nursing and Nursing Education

THE presentation of the report of the Committee on Nursing Education appointed three years ago by the Rockefeller Foundation is an event of notable importance in the history of nursing and of public health. The report is based on an exhaustive survey conducted by Miss Josephine Goldmark which has dealt on the one hand with the actual work of the nurse in public health and in the care of the sick and on the other hand with the facilities provided for her training. The result is a broad and comprehensive plan which must demand the serious consideration of all health workers—both for its own sake and because of the fact that it is sponsored by such leaders in the medical and public health fields as Biggs, Edsall, Welch, Holt, Farrand, and Winslow, and by such prominent nurses as Miss Wald, Miss Nutting, and Miss Goodrich.

The report gives little encouragement to the extravagant claims sometimes made as to the present inadequacy of nursing service but it does recognize that more, and particularly better nurses of various types are needed and it recognizes at least three such types as fundamentally distinct in their educational requirements.

It is first recommended that the partially trained nurse, of whom there are now as many in actual practice as there are fully trained nurses, should be recognized and standardized and licensed under the title of "nursing aide" for the

comprehensive plan so that it may properly advise donors as to the proper field for social and civic work. Naturally the interest in child welfare prompts many people to give to children's charities. Without a plan such giving becomes indiscriminate.

The Community Trust undertook to provide means for the guidance of givers in the field of infant welfare and has succeeded through the report just published in setting forth a "Chicago plan." Elsewhere in this issue is set forth a complete summary of this report. Specifically it recommends that prenatal care be extended to all prospective mothers whom at present it does not reach and that the prenatal care afforded by Chicago's agencies and institutions be coordinated and standardized through a permanent prenatal or maternity council, to consist of obstetricians, pediatricians, social service workers, nurses, and other public spirited citizens.

A minimum standard for prenatal work has been drafted by a local committee representing physicians and nurses and is presented for discussion and possible adoption by all persons or groups concerned in the field.

Such constructive work in health organization is very helpful, and it is to be hoped that similar inquiries may provide the basis for plans in other fields of health work.

### Hunger Phenomena—Mental and Physical

SCIENTIFIC data are not always obtained from the laboratory. Some of the finest observations in botany, zoölogy, and in medicine have been made by men who did not work in laboratories. Occasionally a literary description of a disease, physical condition, or state of mind is just as accurate as one written in so-called scientific language. A case in point is the book "Hunger" by Knut Hamson, the recipient of the Nobel prize.

Hamson has described in this book the state of his body and mind while he was in the throes of hunger. There are many records of fasting people, some extending over periods as long as sixty days, but we dare say that none of them are as clear cut, as vivid, as true as the description by Hamson. In "Hunger" one has an exact description of the hungry man's feelings. Hamson takes hunger from the realm of the body and projects it into the realm of the mind as well. He shows the mental changes a person undergoes during an extended period of hunger, the physical reaction, the philosophical moods, the joy the sorrow, the accompanying despondency. Even when he reaches the far heights of poetry in the descrip-

tion, one nevertheless considers it a true picture of his state of mind. Of course, not every hungry person lives through the same moments that Hamson did. Not every person benefits from life alike; perhaps few persons can be expected to experience the height and depth of feeling that affect a poet of the type of Hamson. He proves, however, that the state of hunger in the body results in a state of mind that is productive of emotion and carries with it profound possibilities of inspiration and depression. It shows, furthermore, that what we are prone to describe as physical conditions of the body are intimately connected with mental and spiritual states. Hamson's "Hunger" should be read by laymen and physician alike, by scientist and student. It depicts the mastery of the human condition and of human affairs. As a human document it rivals Thomas DeQuincy's "Confessions of an English Opium Eater."

---

### The Increasing Life Span in the United States

A COMPARATIVE statement showing deaths and death rates by age groups in the United States during 1910 and 1920 has recently been issued by the Bureau of the Census. This shows that the death rate was lower in every age group in 1920 than in 1910, the most pronounced change appearing in the rate for infants under one year of age which fell from 13,084 per 100,000 in 1910 to 9,660 per 100,000 in 1920, a decline of approximately 26 per cent. In the age group above 75 years there was a fall of about 6 per cent, while in the next lower age group, 45 to 74 years, the decrease was 12 per cent due largely to a lowering of the rates from tuberculosis, acute and chronic nephritis, organic heart disease and typhoid fever. In the decade under discussion, for example, the general death rate from tuberculosis has fallen from 160 per 100,000 to 114 per 100,000; from acute and chronic nephritis from 99 to 89; from accidents from 84 to 71 and from typhoid fever, the remarkable drop from 24 to 8 has occurred.

Nevertheless, the statement that the death rate in every age group is lower in 1920 than in 1910, at first glance appears fallacious because, of course, every living person must eventually die and the best which sanitary science can hope to do is to postpone death as long as possible and to render the years of life economically potential. The data above referred to show that whereas in 1910, 805,412 persons died in the registration area of the United States, in 1920 the number was 1,142,558. If the total number of deaths in

each of these years is distributed by age groups so that the percentage of each of the whole is shown, the apparent fallacy is dissolved and it is seen that there has been a reduction of 4.89 per cent in the age group and below fifteen years and a compensatory increase in the later age groups.

Year—	Under 1 year	1-14 years	15-44 years	45-74 years	75 and over
1920 .....	15.28%	10.50%	24.07%	35.12%	14.96%
1910 .....	19.17%	11.50%	23.21%	33.09%	13.04%

This means an increase in the average life-span since more people are getting into the later age groups before they die. This in turn means a greater economic life span, a longer period of productivity and hence an increase in the national wealth, since it affords an opportunity for the individual to repay society the cost of his care during infancy and childhood. Economic prosperity not alone permits greater activities on the part of the direct health agencies; it brings in its train also those benefits which flow from the full dinner pail, the sanitary dwelling and factory, adequate clothing for protection from weather and predatory insects, good roads, and greater opportunities for education, culture, and recreation.

### Popular Eugenics and its Place in Public Health

ONE of the most important and at the same time, one of the most neglected phases of the public health problem is eugenics and its antonym, dysgenics. To be sure these twin sciences as yet are in their infancy but sufficient progress has been made to warrant their presentation to a general public which is already beginning to manifest considerable interest in the conservation and improvement of the racial stock. The agricultural portion of the community has learned the value of the careful breeding of horses, cattle, swine, and domestic fowls in order to develop certain desirable qualities and once in a while the idea registers that perhaps it is quite a desirable and nearly as practicable, to apply the same methods to mankind. The laws which require the presentation of health certificates by candidates for matrimony have met with ready acquiescence and, although their primary effect has been a certain limitation of the spread of the venereal diseases, they have served to impress upon the subconsciousness of the community the necessity for care in the selection of a mate. Many colleges now give adequate courses in eugenics that will probably aid considerably in the science of being well born. It is believed, however, that the publication of eugenic and dysgenic charts with explanations couched in simple language will be a valuable means of bringing home to the public the fact that certain physical,

mental, and moral traits are transmissible by heredity and that it rests with the individual to determine to a considerable extent the characteristics which his descendants shall possess. To this end THE NATION'S HEALTH purposes to publish from time to time data bearing on the subject and it is hoped that this material will be copied widely and utilized by public health workers generally.

It may appear at first glance that this is a refinement of sanitary medicine which may well wait until we have made a greater impress upon syphilis, tuberculosis, and cancer, until we have reduced the mortality rates from organic heart disease, until man in many parts of the world has ceased to be a collection of ambulatory zoological gardens. In a way this is true, but on the other hand the Church long ago demonstrated the fact that an effective stimulus to present righteousness is a well presented uncomfortable hereafter. Furthermore, heredity is a subject about which human beings have for a long time possessed a lively curiosity, as witness the perpetuation of the prenatal impression myths and the undying story of Jacob's "ringed, streaked, and striped" cattle and the facts of eugenics will find an appreciative audience if they are set forth in readable interesting style. Without doubt much of the work which is being done in the improvement of the environment of man and the elimination of preventable disease, is exercising by a process of indirection a profound effect upon the racial stock. It is equally proper and almost as necessary that the problem be attacked directly.

In spite of this optimism, it is believed however, that mankind as a whole is not sufficiently developed to apply consciously the science of eugenics in a large and practical way, although it should not be forgotten that from the lowest orders of the human race to most highly developed peoples, miscegenation repressed or at least not favored. The intellectuals of every community have always striven to direct their children to the choice of "well-born" husbands and wives. The basis on which choice has been made in the past has been in part intuitive and in part upon the basis of wealth and position. Neither of these is an accurate eugenic yardstick but they have been and still are better than no standard of eugenic measurement at all. A propaganda of eugenics will be welcomed by this stratum of society.

Schools, of course, are ideal places in which to teach the necessity of healthy marriages of good stock but many prejudices against the inclusion of such material in lower school curricula still exist and after all the home is the natural place in which to inculcate these lessons. Thus taught, the child acquires subconscious eugenic standards to be unconsciously applied in after years. The

father and mother who talk to each other about such things plainly and interestingly in the presence of their children give them valuable training without their being aware that they are receiving instruction. The births of household pets serve as object lessons to the children who thus see in a practical way the results of certain crosses and the perpetuation of coat-markings and other physical characteristics. They grasp the differentiation between mongrels and thoroughbreds and with a little stimulation see that the same laws apply as equally and as inexorably to the human race. The great desideratum is the education of the parents so that they may intelligently direct the minds of their children so that their ideas shall be clear-cut and capable of almost automatic application in adult life. In some of the European cities, the health department has an expert eugenic adviser on its staff for the purpose of studying the pedigrees and giving eugenic assistance to those contemplating matrimony. Perhaps we are not quite ready for such an official in the United States but the health officer who will popularize eugenic teaching will meet a hearty welcome and without doubt will accomplish much good.

### Statistical Report of Infant Mortality for 1921

THE annual report of the American Child Hygiene Association, covering 573 cities over ten thousand in population, is an accurate account of recent progress in the saving of lives of infants. There were 746 cities of ten thousand population or over in the 1920 census. Of these 664 are in the Death Registration Area, and returns are made on 573 of these. The report of the Association covers 89.0 per cent of the cities in the Death Registration Area, and 94.4 per cent of the population. Such percentage of error as must appear in the final figures has been reduced to the minimum by special investigations of all excessively high or exceptionally low returns. The figures received show a most remarkable reduction in infant mortality throughout the country. For cities grouped according to population, the rates are as follows:

Population—	1917	1918	1919	1920	1921
Over 250,000.....	95.4	102.3	87.6	89.0	75.3
100,000 to 250,000.....	102.4	113.6	92.2	94.5	77.7
50,000 to 100,000.....	102.4	106.3	106.3	94.0	80.7
25,000 to 50,000.....	101.9	109.4	92.6	92.8	81.4
10,000 to 25,000.....	101.3	114.1	94.7	93.8	82.3
All cities in area.....	98.6	106.7	91.4	91.5	77.9

Owing to the generally lower Infant Mortality Rate in the rural communities, the figures for the entire area may be expected to be four to five points lower. New Jersey is not included in these ratios because her classification does not make her rates comparable to the figures given.

The lowest infant mortality rate in cities over 250,000 is achieved by Portland, Ore., (48 per 100,000) while the lowest rate (24 per 100,000 of any city included in the report was recorded by East Hartford, Conn. The variations in the infant mortality rate are shown graphically in a chart which should be framed and kept for the daily consideration of all city health departments. Lackawanna, N. Y., showing a death rate of more than 250 per thousand, and the three cities registering a rate of 150 would be stirred to make the necessary effort to bring in the next report their rates into more harmonious comparison with the forty-three cities whose rates are fifty or less, or at least they would be moved to make such a study of local conditions as would determine whether climate, industry, community hygiene, or nutritional work is fundamentally wrong. Much difficulty, of course, was encountered in securing accurate data. The quickest way, states the report, for a community to reduce the infant mortality rate recorded against it is to demand registration of every birth, as required by law.

### Smallpox by Popular Vote

SMALLPOX depends on the popular vote. Study of the smallpox statistics in twenty states recently reported by Dr. J. P. Leake of the United States Public Health Service for the last six years and of the vaccination laws in the same states indicate that the people have generally obeyed the vaccination laws that they have made. Wherever popular sentiment has sustained a strong centralized compulsory vaccination act, smallpox is today negligible; where local authorities have been given discretionary powers as to enforcement, invariably the rate has tended to rise; and where the laws have lacked compulsory features or there have been no laws, the rate is high.

In the twenty states considered, four eastern states show a combined smallpox curve that has been at a consistently low level for the six years. Seven southern states and six central states show curves that are much higher and are very similar to each other, though that of the central states is about twice as high as that of the southern states. The three Pacific Coast states show a most extraordinary increase in the disease, the smallpox curve having soared from one nearly as low as that of the eastern states in 1915 to one eight times as high in 1920.

Within each of these four geographical groups the better the status of vaccination in the law, the lower is the smallpox rate. The states where vaccination of school children is generally required have little smallpox, averaging three cases a year

for a community of one hundred thousand inhabitants; the states where there is no such requirement have 113 cases per year for each one hundred thousand persons, a rate high enough to make it probable that one person out of every thirty would at some time have an attack of small-pox.

---

### The Outlook for the Blind

THE first annual meeting of the American Foundation for the Blind was held at the School for the Blind at Austin, Texas, June 28, 1922. Thus the work of the American Association of Instructors of the Blind assumes a permanent character, national in scope, and, in taking over responsibility for the publication of *Outlook for the Blind*, publicity and the vigorous prosecution of an enlarged program of scientific care and training of the blind are assured. The highest credit is due the voluntary organization that has fostered this enterprise and a future of increasing usefulness is predicted for the organization on the new basis.

---

### Homeopathic Physicians Emphasize Public Health

THE seventy-eighth session of the American Institute of Homeopathy which convened in Chicago the week of June 18 to 23 carried an outstandingly good program on sanitary science and public health. Occupation, posture, rehabilitation, medical supervision of industry, skin lesions growing out of occupational hazards, the specific problems of the woman worker were severally discussed and their interrelations brought out as well as the responsibility of the physician for the enlightenment of the worker and for making medical service available and more generally effective.

The most hopeful sign of the times is the increasing amount of time and attention that is being conceded to social medical problems by the physicians themselves. If a short time since the medical profession could be charged with shortness of vision, indifference, and isolation, it is so no longer for individuality and collectively the medical groups are assuming their civic and social responsibility.

---

### Physician, Heal Thyself!

DO HEALTH departments generally practise what they preach? Are they more or less efficient physically than other bodies of professional workers? In urging before the Joint Annual Conference of Sanitary Officers and Pub-

lic Health Nurses in the state of New York the importance as a health measure of an annual physical examination of every man, woman, and child in the state, Dr. Hermann M. Biggs, commissioner of health, made the statement that, though extraordinary valuable in the interest of preventive medicine, and advocated for years by the department, not until recently had the members of the New York Health Department systematically undergone examination. The results were startling in the number of serious and previously unrecognized defects and diseases disclosed, and the results of reasonable care subsequent to these examinations were sufficiently gratifying to extend the practice.

Again we have emphasis that health, the most important asset of any people, needs to be made a definite objective, both in matters of early education and in continuous supervision throughout adult life. Health does not "happen." It is not a gift. It needs to be actively sought, and secured by habits self-imposed.

---

A SENSE of local responsibility for the welfare of the children is what is needed to abolish child labor, declared Herbert Hoover before the National Conference of Social Work in Providence, June 27. Failing in this, an amendment to the Federal Constitution must be sought as the only other alternative to overcome what he considers "a blight that in its measure is more deplorable than war." Forward looking states have passed statutes which fully protect the child in its minority, but there is still a minority of states which are "still in the Middle Ages in their attitude toward childhood." The sense of local responsibility is the only saving grace in this matter, and nothing can be more disheartening than the impulse given to centralization under Federal control by the continuous failure of local government in a matter affecting the nation as a whole so vitally as does the question of child labor. An industry that cannot exist without cheap child labor has no right to exist. A nation that continuously exploits its children is foreordained to fail.

---

THE relief operations of the American Red Cross in Europe were officially closed June 30. Thus closes what has been perhaps the most magnificent demonstration of humanitarian effort ever witnessed. Especially in the field of child welfare have American objectives and American methods served the world. The activities involved have given our own workers a broader outlook, and better organization. The whole story is one of real achievement.

# HEALTH IN INDUSTRY

*Official Organ of the American Association of  
Industrial Physicians and Surgeons*

*Editors for the Association*

THOMAS CROWDER, M.D.

WADE WRIGHT, M.D.

*Officers of the Association*

C. E. FORD, M.D., *President*

C. F. N. SCHRAM, M.D., *Vice-President*

L. A. SHOUDY, M.D., *Second Vice-President*

W. A. SAWYER, M.D., *Secretary-Treas.*

## Some of the Present Issues Before the Association\*

BY C. E. FORD, M.D., PRESIDENT, AMERICAN ASSOCIATION OF INDUSTRIAL PHYSICIANS AND SURGEONS, GENERAL CHEMICAL COMPANY, NEW YORK CITY

THE past year has been a strenuous one in the business world, the changes registered during this period having a very definite bearing upon the future of industrial medicine. The program arranged for the Seventh Annual meeting of the Association is comprehensive in subject material and is calculated to indicate present trends and to point the direction in which constructive effort on the part of industrial medicine needs to be emphasized.

There are a few items in particular that the Association should bear in mind. The period of great business depression through which we have just passed has reacted somewhat upon the particular job with which we have to do. Happily the current has turned in an upper direction, and if the opinion of responsible industrial experts is to be taken seriously, the worst is over and we can confidently expect that our particular work will receive greater attention and larger material support in the very near future. I understand that a year ago, business generally was on about a 40 per cent basis of production and that today it is on a 60 per cent basis.

The basic business of the United States, namely, the iron and steel industry, is, we are informed, on a larger productive basis than ever before in the history of the country excepting during the years 1917, 18, and 19. This means that within a short time this activity will be reflected in general business conditions.

\*Address of the President before the Seventh Annual Conference of the American Association of Industrial Physicians and Surgeons, St. Louis, Mo., May 22-23, 1922.

A considerable effort has been made this year toward increasing the membership of the Association and it has been a fruitful endeavor. The membership has not only increased but it has responded in the payment of dues. The active interest has increased, as reflected by the program we are about to hear, as well as the attendance at this session. Our financial condition is improving, although we still have a deficit, which must lead to some action on the part of this Association looking to an increase of the annual dues. I think it will be wise to levy an assessment of perhaps \$5.00 which would carry us through until such time as a constitutional amendment can be made, thus providing for a greater source of permanent income.

### Fixed Income Necessary

If we are going to accomplish anything as an organization, we must have a fixed income, perhaps much larger than any of us have considered as being necessary. From ten thousand to fifteen thousand dollars per year will be necessary. This will enable us to employ a full time executive secretary as is done by many of the larger and more active public health organizations, as well as the maintenance of a proper medium for our own and general education.

The relationship of the Medical Department to the industrial organization is a question that is of concern to all of us. The activities of the Medical Department are too often under the direction of a personnel manager who perhaps may be wholly lacking in human understanding and

unappreciative of the finer confidential relationships of doctor and patient. Until personnel managers are trained to a better concept of the ethics of the situation and industrial relations are recognized as of sufficient importance to merit the attention of the higher executive, the medical department should be under the direction of, and answerable to, the highest possible executive. This opinion is not based on the desire to set up a false plane of authority or an intellectual aristocracy, for the industrial medical man, but solely upon the observation that the lack of understanding of the medical viewpoint on the part of employment managers has often seriously interfered with measures designed for the benefit of the patient, and, ultimately that of the employer. This form of organization may not be in accord with the theory of scientific business organization, but it is of no inconsiderable practical value.

It seems to me that our members have been somewhat remiss in having neglected their opportunity of making simple researches by known methods of investigation. Many problems confront the industrial physician daily, which involve facts at present unknown that can be established with a very little effort. An industrial toxicology needs to be formulated; dust is a constant problem and it presents a variety of aspects according to the nature of the industry with which it is associated. Special consideration should be given to the relative carbon and silica content of the dust encountered. Many other specific problems

will suggest themselves as observation is extended.

There is one phase of the relationship of the profession, whether private or employed by an industrial organization, apparently in conflict with medical ethics, as now understood, namely, the right of the employer to so-called privileged information in possession of the medical department.

Medical departments are or should be for the mutual benefit of the employer and employed. If the information concerns the welfare of the individual fellow employee the employer's property, or the public, mutual interest demands that it should be commonly available. Bear in mind that this assertion bears only on public rights and does not apply on the fairly well recognized rights of the individual. I believe it must be recog-

nized that industrial medicine is a form of group practice and a modern creation which endeavors to bring together all of the arts and sciences which bear on human welfare. It differs from other practices chiefly in organization which insures coordination of effort, in records based on scientific findings in the special field and a provision for adequate reports considered from professional, legal and economic points of view. However broad the medical service in a given plant may be or whatever support and sympathy the management may have for the medical department, the medical department must sell itself to the individual employee, build up confidence, and earn respect on precisely the same basis as does the private practitioner in his relation to the public.

important part of the convalescent service and very quickly our home was overcrowded. In the meantime we had purchased another property known as the Fairmount Convalescent Home at Matlock, and equipped it for forty women, and, in connection with this home, one room was reserved where mothers could take their babies soon after they were born and remain for a fortnight or three weeks. This has proved to be most invaluable, not only on account of the benefit which the mothers and the children derive, but also owing to the effect on the other women in the home at the time, who have gone there to convalesce, very often in ill health and somewhat depressed, and the interest which the babies have created in their minds has very often largely contributed to their quick recovery. Not only this, but they have learned how a baby should be taken care of.

More accommodation soon became necessary than the Chindrass House for Men provided, and the employers have recently purchased a large property known as "Stubbin Edge Hall," with fifty acres of ground, capable of providing for sixty to eighty male patients. This has just been put into operation and is already paying its way.

This activity, it should be said, and the other extensions of service mentioned herein are quite apart from the government scheme. It is administered under the "Employer's Extra Benefit Fund."

An interesting and highly valuable phase of the health service has to do with maternity care. This was organized through the Central Maternity Ladies' Committee at the Cutlers Hall, Sheffield, which consists of the wives of the directors of the thirty-three works, but principally of the workers' wives of these works. Each separate works has its maternity committee presided over by a director's wife, but consists of at least three-fourths of the workers wives. The ladies on these committees visit the maternity cases and deliver the maternity benefit, either in money or in kind, according to the circumstances which they found. They do more than this; whenever an anticipated birth is notified they go to see whether the conditions are favorable and whether adequate preparation has been made, and if not they give advice and assistance. Every case is visited and reported upon. A distinct fall in the death rate of children belonging to members of the Approved Societies as compared with the national death rate, and the convalescent home at Matlock has contributed very largely to this as, naturally, preference is given to the most necessitous cases.

The work has not been carried out without its difficulties and has required a great deal of perseverance and energy to organize, but has repaid handsomely for any trouble that may have been taken.

The new national program of the Safety Institute of America to curtail the number of avoidable accidents to school children is described in *Safety*.

## Service Self-Administered

THE rapid extension in scope of medical and welfare services in industry, involving many cooperative enterprises and the use of pre-existent voluntary organizations, has often offered complicating problems of administration. Unqualified success has attended the efforts of Sir Arthur Balfour and his colleagues in developing in Sheffield, England a complete industrial medical service on the basis of pre-existing workers' committees. When the National Insurance Act went into effect there existed in most of the industrial plants of England no coordinated system of health provision, but each industry had its own yards club which administered its benefits through the offices of workers committees. Advantage was taken of a clause in the insurance act which allowed of the creation of small approved societies, and thirty-three approved societies were organized, representing the thirty-three principal manufacturing concerns in Sheffield, a central organization being formed which could speak with authority to the governmental department in London. The central organization was put in charge of George Slack, a man of great previous experience with the friendly societies, and members of the staff were placed on the several committees where statistics or the necessary observations were complicated. As a result the work of the thirty-three large works in Sheffield have shown greater efficiency at a lower cost than anywhere else in England. Not only that,

but an extension of activities far beyond the requirements of the law has been made. Of this self-imposed and self-administered service, speaking through the *New York Times*, Sir Arthur Balfour says:

It was quickly found that there was scope for still further activities if the health of the workers was to be looked after and heavy drains on the funds were to be avoided, through either malingering or long and persistent illness. At this stage the employers of Sheffield decided to put together a fund on the basis of a certain payment per head of their workers in the approved societies for the following objects:

- (a) To provide adequate convalescent homes for the workers.
- (b) To provide a system of visiting nurses.
- (c) To provide extra assistance and clothing in maternity cases when required.
- (d) To provide a medical service consisting of specialists.
- (e) To assist in cases where operations were necessary.

One of the greatest difficulties which was encountered was the question of convalescent homes. There are a number of convalescent homes in England to which the central funds subscribe, but we always found that they were very full and our members very often had to wait several weeks before they could be admitted. We therefore decided that we must provide our own convalescent homes.

We commenced with a small home known as "Chindrass House" at Matlock, which was capable of taking twenty men workers. We soon found that there was much to be done by catching the workers before they actually fell sick and sending them to a home for a week or two to save them breaking down. This was not an un-

# Public Health Problems and Industrial Medicine\*

## Practical Application of Public Health Service Activities to the Problems of Industrial Medicine

BY L. R. THOMPSON, SURGEON IN CHARGE, INDUSTRIAL HYGIENE AND SANITATION, UNITED STATES PUBLIC HEALTH SERVICE, WASHINGTON, D. C.

SO LITTLE is actually known of the work of the Section of Industrial Hygiene of the Public Health Service and its practical relation to industry and the industrial physician, that it would seem to be of mutual benefit to the Service, and to industrial medicine briefly to outline what the United States Public Health Service is trying to accomplish in this field of work.

The industrial physician has come into existence largely because of two factors: (1) because the hazards of industry mainly affect the health of the employees; (2) because it has been unquestionably shown that his work is of economic value to industry.

Though we cannot lose sight of the fact that the health of the worker is the hub of the wheel of industrial hygiene, on the other hand, the advancement of industrial medicine may be stimulated more rapidly by convincing industry of the economic value of industrial hygiene. The most important epoch that industrial hygiene has passed through was coincident with the industrial depression that has swept the country since the World War. Previous to this its rapid growth in the United States was due to the enormous increase in industrial operations beginning with the war. Fortunately for industrial hygiene, it was just commencing to offer its wares at the time when they were most salable. Not only were employees interested in what was offered, but industry itself was sufficiently prosperous to lend a favorable ear even to something of which it was not quite sure and did not quite understand. One good resulting from the late war was the rapid extension of industrial medical work throughout the United States. Though industrial medicine slumped with the depression of business in this country, this was logically to be expected, and there is every reason to believe that the recovery of industry will also see industrial medical work reinstated on a more substantial foundation than before the war.

What happened to industrial medicine in connection with the recent business slump? In the great majority of instances, the industrial medical division decreased in proportion to the general slump in that particular industry; in some instances the depression was somewhat greater than the general business depression. Either of these changes was to be logically expected and outside of the temporary inconvenience, no permanent harm has been done, for the medical work will return to normal as business becomes normal. In a very few instances the industrial medical work has forged ahead, suffering no actual reduction, but in reality expanding. One such plant as this I visited not long ago in the central west. In such instances as involved abandoning the industrial medical work, the industrial physician, no matter what excellent work he may have accomplished, failed in one important point—he failed to demonstrate his economic value to the plant officials. There will probably never be another epoch in industrial medicine that will point out more clearly the necessity of demonstrating the value of industrial medical work than the one we have just passed through. I dwell with emphasis on this subject because the work done by the United States Public Health Service in industrial hygiene aids the industrial physician in presenting the value of his work to industry.

### Parallel Developments

The literature of the development of industrial hygiene brings to notice the correlation between industrial laws and the progress of industrial hygiene. In every country studied by the Department industrial laws have antedated industrial medicine, except in those industries which have advanced on their own initiative. The formation of industrial laws is not a simple problem; basically the law is for the protection of the industrial worker, but in promulgating such a law it is necessary to take into consideration its effect on industry and the cost of production. To specify the same standard of illumination for coarse

work as for fine clerical work might be esthetically desirable, but it is neither necessary nor economical. Elimination of all dustiness in a work process where there is a dust hazard might also be desirable, but there is certainly no scientific reason for such a demand if the dust itself is not a specific poison. Not long ago it was the idea of many sanitarians that every city emptying its sewage into a stream of water should be compelled first to treat this sewage to such an extent as to render it entirely innocuous. Now the demand is that cities treat their sewage to the extent that other cities located on the same stream may take their water supply and with reasonably adequate treatment render it safe for drinking purposes. The same view must be held regarding industrial laws. The law must protect the worker against the health hazards of his work processes, but regulatory measures must be based on scientific investigations so that when this main requirement is satisfied they may avoid needless and unnecessary requirements which increase the expense but do not provide additional safeguards.

Part of the program of the Industrial Hygiene Section of the United States Public Health Service contemplates investigations of this sort. The illumination and dust hazards previously referred to are two important health problems of this kind which have been the subject of recent study by the Department.

The standards of illumination have been rather completely considered, but the field is large and there is still need for further investigation. Increased production and decreased accidents have been demonstrated as closely correlated with good illumination. There are many points, however, on which it would be desirable for the industrial physician to have more data which might afford better basis for his demand for the increased expense of improved illumination. What is the actual increase in efficiency under good illumination as compared to poor illumination? What is the difference in the visual fatigue in employees with normal vision and

\*Read before the Seventh Annual Meeting of the American Association of Industrial Physicians and Surgeons, St. Louis, May 22-23, 1922.

those with certain defects in vision and sight in poor and in good illumination? What types of work are best suited to different eye defects to give minimum fatigue to the eye and maximum production? What amount of physiological fatigue to the retina and eye muscles is caused by different kinds of work under different degrees of illumination and different types and colors of light? These are some of the more important questions we have undertaken to solve in our studies of eye defects among the post office employees of the government. We have been fortunate in this study to have the advice of some of the best practical illuminating engineers in industrial work, the complete cooperation of the post office officials, and the good will and assistance of approximately 3,100 employees who have willingly submitted to examinations and tests of efficiency. Some of the questions above propounded will in all probability be satisfactorily answered with the publication of these results, which will be in about six months. The fatigue work will require a longer time.

### The Dusty Trades

The dust work now being carried on by one of our engineers under the direction of Professor C.-E. A. Winslow at Yale and in cooperation with the Bureau of Mines at Pittsburgh is a part of a very extensive and practical program. The South African workers, after intensive study for which the rest of the world must be eternally obligated to them, have chosen certain standards for dust measurements. They have also arrived at some rather definite conclusions as to the size of the dust particle which are to be considered as the most dangerous to workers. These conclusions, however, represent a rather limited class of dust and in this country, where hygienic measures must deal with many classes of organic and inorganic dust, conclusions on the basis of the African data are not sufficient. The high points in the program of work undertaken by the Public Health Service are as follows: (1) A study to determine the best methods of collecting dusts of the various classes; (2) a study from post mortem examinations to determine the measurements of the dangerous particles in the various classes of dust; (3) a study to determine specific standards of dustiness for the different classes of dust; (4) morbidity and mortality studies to determine the relative harmfulness of different classes of dust. The studies of illumination

and dustiness are of value as scientific research, but their greatest value lies in their practical application to the industrial worker and industry as a foundation for practical industrial laws on these subjects. Furthermore, the necessity of their application to the worker and industry, coming as it does within the province of the industrial physician, is an important factor in broadening his field of work.

The research on illumination and dusts has been spoken of because of its bearing upon the framing of industrial laws, but the scientific work of the Service does not end with these two subjects. As every industrial physician knows, the scientific investigation work to be done in regard to the health hazards of industry is endless because of the complexity of the work processes involved in the present day factory. The work of the Service in this field will only be briefly touched upon in order to indicate its general trend. In the past year we have made a contribution to the study of cutting oil dermatosis in the nature of suggesting a method for its prevention. At the Hygienic Laboratory we have been studying the relation of zinc to brass founders' ague, as suggested by Lehmann, and the occurrence of zinc in food stuffs and in the normal tissues of the body. The results of these studies will be known in the coming year.

With the excellent assistance of Professor Frederic S. Lee and Professor Scott of Columbia, and Professor Adolph of Pittsburgh, the Public Health Service has been engaged in the study of physiologic effects of fatigue, and during the present year the investigation will also include a study of high degrees of temperature and humidity and their association with the production of abnormal fatigue.

At Hagerstown, Md., in connection with the general studies of the causes of sickness in normal groups of population being carried on there by the Public Health Service, the Rockefeller Foundation, Johns Hopkins University, the State Board of Health and other organizations, a similar study of cement workers has been undertaken. This study is expected to cover a period of from three to four years, and should furnish excellent comparative sickness records to determine the effect of this industry—which has always been said to be a harmless one—on the health of the workers.

In our studies of the physical defects in workers in various trades, beginning with Dr. J. W. Schereschewsky's study of the garment work-

ers, extending to the present observations on glass workers, and including employees in the steel, chemical, cigar, and pottery industries, the fact is outstanding that almost consistently a higher per cent of physical defects occur among employees with bad posture than with those with good posture, age as a factor being ruled out. As an instance of this, in 5,392 examinations the rate of suspected tuberculosis cases per thousand employees was 49.5 in persons with good posture against 71.4 in those with bad posture.

The subject of posture therefore becomes highly important. It is not desired to imply that the Public Health Service studies alone have brought out the significance of this subject. The studies of Dr. J. E. Goldthwait and others have emphasized its importance; however, from an industrial standpoint such extensive observation is called for that the Public Health Service plans to make exhaustive investigation of the effects of good and bad posture on the health of employees, and of the factor of the work processes in the causation of bad posture.

### Physical Defects in Workers

It is only possible to touch briefly on the investigative work of the Public Health Service. Dr. C. E. Ford, in the last issue of the *Journal of Industrial Hygiene*, states:

The doctor who accepted employment as an industrial physician merely to run a dispensary for emergency service, or to fill his wards for teaching purposes, or to protect the interest of his employer in the case of liability claims can hardly be considered an industrial physician in the strict sense. The greatest shortcoming on the part of the physician in industry from a strictly medical viewpoint is his neglect of research. Investigation and inspection of plants disclose innumerable opportunities for saving measures in illimitable variety.

What the Public Health Service has done in its investigation work is of use to the majority of industrial physicians and may be applied in a practical way to their every day work.

Mr. Sydenstricker of the Public Health Service presented to this Association a plan of assistance through the analysis and interpretation of industrial sickness records. It should be noted in passing that up to the present time our knowledge of the relative dangerousness of various health hazards has been gained from mortality records, largely kept by insurance companies. The analysis of these records has been of the utmost value to the industrial physician, but as in general public health work, mortality

records only represent the end result. They do not tell the story of the sicknesses during life, nor are they of great value to the health of the worker while he is alive. Industrial sickness records bear the same importance to industrial medicine as morbidity records on communicable diseases do to epidemiology.

Many industries keep records of sickness in which small groups of workers are exposed to certain definite health hazards. Though in an individual industry the group may be too small for statistical analyses, a combination and correlation of the records of these small groups in several industries would reveal a clear-cut picture of the influence of a given hazard on the health of the worker.

This cannot be accomplished in a day. It is first necessary to provide records which are comparable. In many industries this will involve the cost of making the preliminary change, but to offset this first cost there is certainly a secondary saving. Such standardization by records not only makes it possible to compare one industry with another, an item of great economic value in the estimation of the efficacy of industrial medical work, but it opens the way for scientific research in industrial morbidity records with relation to specific health hazards.

An additional thought in regard to industrial sickness records was suggested to me by Dr. Otto P. Geier of Cincinnati, and its development will be an invaluable contribution to medicine. No other records of sickness give us as accurate a history of the individual as do our industrial morbidity records. The family physician does have to a certain extent a mental picture of the past illnesses of his regular patients; some few have written records, but they are certainly in the minority. The specialist may obtain a fairly accurate history of his patient's past, and the pathologist may give us an end picture from which to reconstruct a past history, but none of these men has a daily record year in year out of the physical condition of the patient, his variations in efficiency, all of this information tied to a preliminary physical examination of the individual at the beginning of the period of observation. Nowhere except in industrial morbidity records can such a history be found.

What does this mean to medicine? A worker for the first time shows the clinical signs of tuberculosis. From his industrial record we are able to gain a clear view of the nature of the

illnesses he passed through for several years back and the effect of the disease on his efficiency record. One such case would be negative. But if cases of this sort appearing here and there in the records of many industries provide a picture of the developmental period of tuberculosis, that is invaluable to the clinician. Such a study is contemplated for the coming year, and a report on the results of the work will be made at the next annual meeting of the Association of Industrial Physicians and Surgeons.

One more point arises from the tendency of individuals and corporations to write the Federal Government for information on industrial subjects. It has been necessary for the Public Health Service to develop a consultation service to meet requests pertaining to industrial medicine and industrial hygiene and sanitation. These requests are of all sorts and types: from the individual worker who is interested in the effect on his health of the special work process he is engaged in; from the industrial physician who meets with a special health hazard, and has neither the time, the library, nor the laboratory to work out his problem; and lastly, from the industry itself which is engaging in a new class of work and desires to know the hazards to be expected and the means of prevention.

In the majority of instances we do not have the funds nor the time to work out the individual problem, but from the Congressional Library, the Library of the Surgeon General of the Army, and the consultants of the service in industrial hygiene who are authorities in their individual lines, we are usually able to answer the inquiry by giving an outline of practically all that is known on the subject in this country and abroad. The consultant service has been developed to meet the present demand and it has been of practical assistance to all classes of people interested in industrial medicine. On all points in which this consultation work can be of assistance to any industrial physician, industry, or employee, the service is cheerfully extended.

This paper was not designed to bring out any special scientific facts; it only sets forth briefly the work of the Industrial Hygiene Section of the Public Health Service so that the Service and industry urge a better mutual understanding in the great field of work of industrial hygiene. Primarily what we have tried to keep in mind in the Service work is its practical value to the industrial employee and to industry. We have

neither the funds nor the personnel to take up the study of all the important hazards that affect the health of the industrial worker; but we have tried to keep relative values always before us and to select for investigation the industrial problems that affect the greatest number of workers and the elimination of which, like the elimination of the more important communicable diseases, will have the greatest bearing on industrial morbidity rates.

### Formula for Denatured Alcohol

The following formula, to be known as specially denatured alcohol Formula No. 46, has been authorized by the Commission of Internal Revenue for use as antiseptic, sterilizing and bathing alcohol by visiting nurse associations, public nursing associations, clinics and dispensaries, exclusively. To every 100 gallons of pure ethyl alcohol add 25 fluidounces phenol, U.S.P.; 4 fluidounces oil of wintergreen or methyl salicylate, U.S.P. This formula, the commissioner states, will only be authorized for use by institutions and organizations named above which are of a semi-public character and engaged in charitable work.

### President-Elect A. M. A.

Keystone View Company, Inc.  
Ray Lyman Wilbur, M.D., president of Leland Stanford, Jr., University, who was elected president-elect of the American Medical Association at its annual meeting in St. Louis. Dr. Wilbur received his M.D. degree from Cooper Medical College, San Francisco, which later became the medical department of Stanford. From 1911 to 1916 he was dean of the medical school and in 1915 he was chosen president of the University. During the war Dr. Wilbur served as chief of the Conservation Division of the United States Food Administration.

# Economic Levels and Tuberculosis Groupings

## Natural Social Groupings, from Standpoint of Contacts, Supplant Other Points of Approach

By WILLIAM CHARLES WHITE, M.D., MEDICAL DIRECTOR, TUBERCULOSIS LEAGUE OF PITTSBURGH, PITTSBURGH, PA.

THE war against tuberculosis has too often degenerated into a war against the individual suffering from tuberculosis. Tuberculosis of all diseases is probably the most nearly universal; in fact, we scarcely needed the figures and careful work of Opie to confirm those of Naegeli and Burchhardt to illustrate that all adult humans living in civilization experience an infected period as also do many children, food-producing animals, and, less frequently, birds and other mammals under captivity.

It has other characteristics of equal importance. More than 90 per cent of tuberculosis as it infects mankind is in the lungs, where it may be harbored even in open form for a whole lifetime without producing the external signs of sickness. In fact, many tuberculous patients, after the morning cough and expectoration clear out the sputum for the day, show nothing to expose their illness to the world and often appear fat and healthy. It is thus easily a hidden disease. It differs in this way radically from those other infections which even the untrained eye readily detects, such as cancer or smallpox, or which produce a malaise and evil feeling against which the body and even the mind is no proof, such as diphtheria, or malaria. It therefore does not subject itself to the rigid laws of control of epidemics with which we have become familiar.

Probably no other illness permits of so great a carelessness. The discharge from the lung can go no place else but into the mouth by way of the throat and what is more simple than the expectoration, which Dickens described as one of our national characteristics, yet this is the method by which new cases of tuberculosis are produced. Let me repeat. It is a universal infection, the cause of 10 per cent of our sickness; and during a great portion of this sickness it is easily hidden and thus becomes a problem not lending itself to laws and police authority and is spread by one of our bad national habits—spitting.

*Flexibility of organization is the keynote of modern medical service. Mobile dispensary units make possible the observation of affected groups on the basis of individual activities and group contacts. The individual is reached without loss of his social perspective.*

*This system really eradicates foci of disease and enables the treatment of the affected individual without making him an economic burden or a social pariah. Incidentally economic and industrial relationships of great moment are thereby disclosed.*

Another curious feature of this disease is its steady decline from the beginning of our statistical records. During this decline there have been great discoveries; by Villemin, of its infectious character; by Robert Koch, of its cause; by von Pirquet, of a biological test to detect the presence of infection; by Trudeau, and others, of its curability based on physiological laws. There is no place on the declivity of the mortality rate to indicate these momentous discoveries in the history of this sickness. Other diseases, like the great influenza epidemic, come and despoil the curve from time to time but its downward course is unimpeded. In fact, so low is it in modern, new, and healthful cities that one hears occasionally the cries of the victorious crusaders who expect to stamp it out within a few years. It is, however, a greater problem than this. There is undoubtedly an irreducible minimum below which, with our present knowledge, we cannot descend. Epidemiologists since the war are questioning the tuberculosis problem anew. The more rapid decline of the last two years has raised many questions with no satisfactory answer; but there is one graphic expression by an unknown author who says we have "burned a hell of a lot of sputum in the last ten years," and this may explain part of it.

Among the more specific questions facing us today are the variations in racial susceptibility. A new impetus to this has been given by Dr. Paul A. Lewis of the Phipps Institute with his study on laboratory animals of the varying susceptibility of races. So careful has been the work that it is possible for him to trace the presence of his most susceptible race through all intermarriages with those of less susceptibility. We find the same question arising bountifully in the literature on the susceptibility of human strains, the varying susceptibility of the Irish and the Italian strains, the question of chronicity surrounding the Jewish stock, and now the varying picture presented by rural and urban communities mainly on the basis of the mortality rate.

We have had from the laboratory differentiated the well defined strains of tubercle bacillus, mainly the bovine, human, and avian strains—and now comes from the statistical department, mainly through Professor Brownlee's studies, the suggestion based upon the statistics of England and its cities and counties that there may be even among the human tubercle bacillus strains of varying character, one producing young adult tuberculosis and another adult strain producing old age tuberculosis with possibly a middle adult strain each varying in characteristics much as typhoid and paratyphoid organisms do. If this be substantiated, an entirely new ground is opened for study on the laboratory and clinical side.

One other field of activity has been opened up in this country in the University of Chicago by Dr. Long in an attempt to reclassify what is known as the acid-fast bacilli, to which the tubercle bacillus belongs, on the basis of their primary metabolic functions. Dr. Long allows each strain of bacillus only one way of securing its nitrogen at a time and has given us most interesting new thoughts on the life of the tubercle bacillus itself. In fact, at the recent meeting of the National Tuberculosis Association Dr. Long announced that from his studies in connection with Dr. Treat Johnson of Yale it is apparent from the chemical composition of the tubercle bacillus

\*Read before the seventh annual meeting of the American Association of Industrial Physicians and Surgeons, May 22-23, 1922.

that it does not belong, as we have always thought, to the plant group but rather to the animal group. These items indicate some of the complexities of this universal infection.

In the past twenty-five years there has gone on a very active crusade with the intention of eradicating this illness and we have directed our activity largely to the social groups which have a political basis; that is, we have taken nations, states, counties, cities, and city squares, simply because they were the most common limitations of human aggregation. During the past few years, however, the lack of cohesion in these social groupings has been evident to many as among the weaknesses of our methods and many thoughtful men have searched for a more cohesive grouping of society in which to work.

In a re-study of the various groups of society of which the main ones are the political, the religious, and the industrial, the industrial group is probably fundamental to the rest in every day life from the standpoint of cohesion and there is at the present time a well defined shifting of the ground of the tuberculosis activity to the industrial groupings. In ordinary life man's thought and interest are largely centered in that phase of his existence which satisfies his material needs. The mass of men and women devote one-third or more of each day to their industrial group living, one-third for sleep, and one-third for meals, pleasures, and all other activities; so that from this standpoint, also, it is the most important grouping arrangement. In this industrial life that care which will give the worker the maximum number of hours of labor under the most secure conditions of health, and the employer the full return for the wage agreed upon with the least loss of time from any of the irritations of ill health, will bring about the happiest result. Therefore tuberculosis forms a very important element by virtue of its chronicity and characteristics noted above in the whole program of health in industry.

Three great features of the tuberculosis control are; (1), the detection of cases needing care; (2), the detection of cases who are able to work; and (3), the examination of all households in which tuberculosis is found to be present. These can only be accomplished by the periodic examination of all employees and employers working in a plant and the examination of all applicants for employment.

For this purpose there has been devised what may be termed a Mobile

Dispensary Unit. This consists of a group of doctor, nurse, and clerk and periodically a laboratory worker, an operator of portable x-ray machine, and some portable equipment. There is provided in each plant a room with such physical equipment as is constantly needed. In such examinations many questions of tact arise. Any disturbance of the industrial plant must be carefully guarded. The fear which examinations create among the ignorant must be cautiously dealt with. Each patient requiring care must be handled as an individual and not simply as a cog in a great wheel. In the past our dispensary work has been wholly different. It has been required that those sick had to make the journey to the dispensary wherever it was located. In the new plan the assistance is carried directly to the place where the examinations are made with the least possible disturbance both to the industrial activity and the time of the earning member of the working force.

It is a very common thing today for plants to look upon their welfare departments on the basis of return on investment. Careful examination of work people before they enter the plant can soon be shown to meet this point of view. But one of the weaknesses of this in community life has been the lack of provision for those that are discarded as a result of medical examination and their rehabilitation. Time will not permit me to describe the devices for correcting this.

In the experimental work in connection with industries which has been carried on in recent years there have been many discussions between labor unions and employers on the authority or privilege of employers to insist on medical examination and it has been necessary to devise some plan whereby these examinations are dominated by neither union nor employer. Our own suggestion and plan are that both employer and union join in securing their examinations and readjustments from service organizations in which both can meet on common ground and on the one hand conserve the interest of industrial plant and on the other, the rights of the employee, but this work has not gone far enough yet clearly to define the proper methods. One of the most important phases to be dealt with is the care of the sick in relation to the earning capacity of the family group to which the invalid belongs in such a way as to secure a return to health at a price that can be afforded.

Many devices for accomplishing this have been offered. It is so impor-

tant a matter, however, that it will likely become the work of a new department of rehabilitation in the service which is rendered to the industry.

Much more difficulty is probably offered by the tuberculous man himself in industry. There is a rapidly growing number of those who should be not only living and working but should be encouraged as rapidly as possible to return to their work or, in many instances, never to leave their work. Any man in whom the industry has years of training invested is an enormous asset up to the period of his defection after which the industry of course must in justice carry the man until he becomes an actual loss.

Instead of pursuing the course of the past of getting tuberculosis out of the industry there is necessarily undoubtedly a new counter movement to get tuberculosis back into the industry with safety. The longer I work in this field the surer I am that a vast number of tuberculous individuals need never give up their labor. Two or three examples will illustrate this point.

The cases of two brothers, the sole support of their mother, appeared within two months of each other. One had advanced tuberculosis requiring absolute rest in bed; the other had early open tuberculosis with three months to secure his papers as a journeyman in plumbing. The whole group of mother and two sons formed an economic unit. By careful planning the mother undertook the care of the sick son at home and the second by intelligent cooperation was able to continue at work, returning to rest at four-thirty and remaining in bed until seven the following morning, when he arose and went to work. This has now gone on for over a year and both boys are apparently recovered; one at labor with care of not only himself but his fellow workmen and the other under strict supervision of visiting nurse and doctor, the mother acting as nurse to both of them. So the economic unit was conserved.

Another case involved one of the employees of one of our steel companies, who after six months in the Agnes Memorial Sanatorium returned home with afebrile, open tuberculosis to find his wife had become during his absence an addict to drugs and liquor. He could find at home no care and rapidly lost all that he had gained in his period of cure. After discussion with his employer in the steel company he was allowed to work four hours a day. Arrangements were made for the care of his wife in an

institution and of his son with relatives. He was taken into a night camp and during the last several months has steadily gained not only all that he had lost but is now in far better shape than when he returned home. An so on, may be cited innumerable cases high and low which with individual care and good judgment can continue earning even though enormously disabled and yet at the same time recover from their disease.

But this involved another question. We are geared in the world to normals based upon anatomy and physiology. This is not a normal for industry. Let me illustrate again what I mean. Three men entrusted with a problem of universal importance met the other day in a large hospital office. Before entering upon the technical discussion which they were there to pursue, they began inquiring about the health of one another. One had advanced tuberculosis and cancer, both apparently for the time under control by hygienic care and operation. One was terribly disfigured from the burns of x-ray. One had advanced tuberculosis and severe injury from a railroad wreck. Not one of them could have passed the draft of an army examining board or of an industrial medical office, yet all three of them were supporting not only themselves but their wives and children, the smallest family of the group being three children. They combined for the time the best knowledge in the country on one of its most important technical questions and were entrusted with its solution. Since seeing that meeting I have been giving much thought to a new standard which must be established in industries which I have called the economic normal. By this I mean what constitutes the limit at which a man ceases to be of full use to the industrial world. When does he cease to be an earning factor in any way in the world, and what provision must be made for him in the several stages from full earning capacity through partial earning capacity to complete dependence upon others?

It is a most important question and yet I believe that its solution is possible through a study of tuberculosis in its relation to industry and I am quite sure that a large number of people taking the cure for tuberculosis today should never have left their labor, but should be using the hours which exist between the time they leave their occupation and the time they enter the occupation in the morning in taking the requisite amount of

rest and care to keep them as earning factors.

More than this, it becomes an important duty of every physician and examining officer to secure for every man in the industry, after training, the maximum number of hours of earning which the partially disabled one is able to accomplish.

## Recent Compensation Decisions\*

**T**HE question of a cerebral hemorrhage came before the Supreme Judicial Court of Massachusetts March 3, 1922.

The decedent, employed as a baker, was preparing to put dough into an oven when he slipped and fell . . . While the decedent did not become entirely unconscious and "kept crying about his head saying that he felt badly" and died within fifteen minutes at the hospital to which he was immediately removed, he made no reference to the cause of his fall; nor did it appear that the fall caused any external physical injuries. The record of the hospital properly received in evidence showed that the patient was admitted in a state of collapse from cerebral hemorrhage.

The question of temperature of the working place was passed upon. "Assuming that in this case the decedent was a man fifty-seven years of age and working in a bakery with a temperature very high, would you say that would probably cause a cerebral hemorrhage?" The claimant's medical expert replied: "Yes, it is probable that the high temperature produced an intro-cerebral hemorrhage. It was an intro-cerebral hemorrhage in this case." The decree was affirmed and the award upheld.—*Feldman's Case*, 134 N.E. 251.

**T**HE following case was decided by the Supreme Court of Tennessee, December 19, 1921. It seems that Milner was a cook for the Patten Hotel. On May 24, 1920 while employed in the performance of his duties in the hotel kitchen, he became too hot "and was stricken with a fainty feeling." He stepped into an alley for the purpose of getting some fresh air. "While standing in the alley at or near the door he fainted, or swooned, and fell, and his arm was run over by the rear wheel of an automobile truck that was passing along the alley. . . . He was immediately carried to the hospital in an unconscious condition and soon thereafter lockjaw set up from the injury

If this plan becomes an economic principle in this country that more probably will be done for eradication of tuberculosis than by any other single influence offers because on such a plan we will get rid of great wastefulness and produce a vast amount of happiness that is not in existence in this field at the present time.

and caused his death."

A portion of the opinion of the court is quoted:

We think that there is material evidence tending to show that the injury which resulted in the deceased's death arose out of and in the course of his employment. There is material evidence introduced tending to show that he became overheated while performing his duties as cook in the kitchen and became fainty, and stepped into the alley to get some fresh air, and fainted and fell, and his arm was run over by one of the wheels of the passing truck. There is also evidence tending to show that the kitchen in which deceased washed was always very warm, and that it was frequently necessary for the employees who worked in the kitchen to step into this alley for the purpose of getting fresh air. . . . The deceased's overheated and fainty condition arose out of his employment and it was on account of this condition that he became exposed to the danger which produced the injury. We, therefore, think the necessary causal connection between the employment and the injury appears.

The case was thrown out because of lack of notice.—*Patten Hotel Company v. Milner*, 238 S.W. 75.

**I**N a compensation proceeding in which it appeared that the employee subsequent to the inquiry went to work for another employer, and that there was a recurrence of the hernia which had resulted from an injury received while working for the first employer, the Supreme Judicial Court of Massachusetts, March 6, 1922 held that it was a question of fact for the Industrial Accident Board to decide whether this condition had a causal relation to the original injury and to warrant its findings in favor of the employee. There was evidence to warrant the findings and the decree was affirmed.—*Goglione's Case*, 134 N.E. 240.

It is reported that the Rockefeller Foundation has offered to Indian medical graduates, selected by the scientific board of the Indian Research Fund, five scholarships of \$1,000 each, for the purpose of graduate public health work in America.

# Mercantile Hygiene in the Health Program\*

## Survey Shows Need of Mercantile Hygiene and Benefits Therefrom

BY ARTHUR B. EMMONS, 2ND., M.D., DIRECTOR, HARVARD MERCANTILE HEALTH WORK, 3 JOY STREET, BOSTON, MASS.

THE success of industrial medical supervision has stimulated twenty-five stores in six cities to finance a five year study of store health. One half of this time has elapsed. The preliminary work of sanitary surveying is completed. In some cases, organizing and developing health services in these stores is now well under way. Records are being standardized and reports are coming in from a number of the most progressive stores. It is proposed in this paper to outline the health aspect of the working conditions in stores; to indicate in general the physical condition of the store workers in these twenty-five stores; to describe the activities and results of the store health departments; finally, to suggest the possibilities of professional usefulness in applying industrial hygiene to this field of community life.

The object of a store is to sell goods at a profit. In storekeeping the stage is set somewhat differently from that in industry. The customer is the real store boss. In one large store approximately one-third of the workers are salespeople who must meet the public. Nearly one quarter of the store force do office work. The remainder are occupied in buying, receiving, marking, altering, packing, transporting goods, besides various occupations, such as window decorating, carpentering, engineering, painting, cleaning and educating. Women predominate about four to one in store work, though this varies much in the different types of stores.

Little time is spent in teaching English to the foreigner, though some is spent teaching better English to the American. A larger amount of formal education is demanded of the applicant to store work than of the industrial operator. Native ability and self-education are gradually giving place as the predominant factors in education among storekeepers. More systematic and more specific education for the job is evident. Inbreeding, promotions from within the store, is preached and is still largely practised by most stores under the name of loyalty. The narrowness re-

sulting is not unlike that seen from inbreeding in college faculties. Most workers have at least a fair wage to begin with and often opportunity to increase it with increased productiveness. Demand and supply largely govern the wage scale.

### Working Conditions in Stores

Behind the scenes in stores will usually be found the evidence of the management's estimate of the value of sanitation and hygiene within legal limits. The management's estimate of the public's demand or appreciation of these health measures will be found in the public selling spaces. Altruistic customers often write the management concerning lack of ventilation or the provision of seats for salespeople.

It is hopeful to find new store buildings reflecting modern sanitary knowledge. Store sanitation varies, then, partly in accordance with the legal limitations and with the age of the building, but chiefly with the management's opinion of hygiene. Store physicians seldom have had time or inclination to concern themselves with sanitation. Such things have usually been delegated to the engineering department. In a previous article<sup>1</sup> the usual faults or omissions have been pointed out in regard to ventilation, overcrowding, lighting, locker rooms and toilets, unnecessary fatigue due to improper seating<sup>2</sup> and incorrect shoes<sup>3</sup>, elevator service, store cleaning and dust.

The sanitary situation, however, may be summed up as follows: Working conditions in the twenty-five stores studied are, in general, good. There are defects in nearly all stores, but sanitary conditions with the possible exception of improper ventilation are not, in my opinion, one of the major causes of the large amount of ill health found among store workers. The major causes of disability have to do in a large measure with the individual vigor and health of the workers, with their health habits, their

health opportunities and their health intelligence.

### Employees' Physical Condition

The physical condition of the employees of stores, as judged by the standard set by college men and women, is, with some exceptions, far below par. The impression is gained that most store people lack a large reserve of physical strength and resistance. This impression is confirmed by the large number of those leaving for ill health, those absent on account of ill health, and the surprising number coming for health advice to the health departments in the stores.

Physical standards for store workers are lacking. A few stores have been making physical examinations for varying periods. Other stores are preparing to examine all applicants and give periodic re-examinations. Satisfactory standards of vigor as well as absence of defects remain to be developed.

Kellogg<sup>4</sup> of Pittsburgh reports the findings from over 1,200 store workers by age groups, 95% to 99% showing from one to five defects. Contrasted with this the report of Lee<sup>5</sup> on the incoming class at Harvard College and the School of Business Administration, a total of over 1,200 men, showing only 5% having defects. Both observers attribute the physical conditions, bad and good, to preventive medicine, its lack and its results. One emphasizes the lack of health habits and health knowledge. The other attributes success to the training by intelligent parents and school health work. The chief cause of store ill health, we believe, is lack of correct early nutrition and training in health habits. In all fairness the college men must be considered a selected group, but they strikingly illustrate the possibilities of preventive medicine and good hygiene.

Store executives represent the key men and women of the enterprise. Their health cannot safely be excluded from medical supervision. The "nervous breakdown" due, I believe, to fear and worry, rather than over

\*Read before the American Conference of Industrial Physicians and Surgeons, St. Louis.

work, is too prevalent to await carefully detailed study to disclose its frequency. There is little doubt that the causes and prevention of much of this nervous exhaustion as well as other physical ills will be discovered as our vision is extended to store health work.

The Dennison Company in its factory in Framingham, Mass., has already demonstrated the value of health work with its executives and has developed a successful method of medical supervision. Here is a fertile field for physical but especially mental hygiene with promise of profitable results.

Accidents and acute illness are usually provided for according to legal and humanitarian requirements in stores of one hundred or more workers. The idea of a modern store health department, similar to the best in industry, as a business asset has not as yet been accepted by storekeepers in general. A good number of the most farsighted merchants, however, have accepted this idea and are engaged in developing the best administrative methods. These methods vary from what is commonly known as the "one man store" methods to that of the health department managed and at least partly financed by the Mutual Aid Association. The health problem in stores naturally pertains less to accidents and more to illness than in the industries. The quantity of work in

well developed store health departments may be illustrated by Chart I.

Illness Classification

The classification of cases coming to the store health departments has constituted a progressive study. A daily report sheet with the chief complaints recorded by the nurse was the first step. Next came the grouping of these complaints according to frequency. Chart II illustrates this grouping for the month of March in one store with a population of about 3,500 people and a total number of new cases of 1,495 for the month. Three were 1,210 diseases, 159 industrial accidents, 126 other injuries, and 1,051 revisits—making a total of 2,546 health department visits and 412 home visits.

The professional medical opportunity in stores is comparatively small if looked at through the eyes of the conventional doctor, whose standard of satisfaction is major medical or surgical care. Such a man would say "tiresome trivial routine." Few pneumonias, typhoids and abdominal operations will fall to his personal care.

To the man with medical acumen and administrative skill, however, there is a large opportunity to be of service in a store. He will father a group of workers who need temporary relief and steering advice with follow up, together with health supervision, and education. He will find many common colds, backed by a variety of nose and throat conditions, treated with home remedies reflecting the hesitating and vacillating voice of the medical profession on this subject supplemented by the free advice and tasty prescriptions of the drug clerk. The upper respiratory tract costs these workers and the store much time, money, and vitality.

The next commonest group of complaints are those of malnutrition and indigestion. The problem is largely one of health education in an adult group. To replace haphazard personal hygiene in an industrial age group with sound health habits will require knowledge, tact, and salesmanship. The group of "Nervous System, Functional" is a real opportunity for intensive study. Fear, worry, and anxiety may be found often in an exaggerated form in stores both among the humble and the exalted.

Here, too, in stores, lies a professional opportunity to study the very beginnings of disease. Patients come freely to store health departments on store time if they receive sympathetic,

Chart II. Classification of diseases and injuries in a store with population of 3,500.

intelligent care. They wish to learn if their annoying symptoms mean beginning preventable illness or are transitory and self-limited. To sift these cases wisely, dispensing health education with relief, requires that the doctor and nurse not only be students of disease and human nature but also health educators.

The coach of a foot ball team develops the highest type of team work. The store management faces this problem of team work among a group much more difficult to coordinate. The success of the enterprise depends directly on the amount of intelligent coordination developed. A large and important part may be played by the intelligent store doctor.

Early industrial and store medicine, confining its activities largely to covering the accidents and emergencies, remained as an outside accessory. The health department, which not only covers emergencies, but seeks to prevent illness, to protect from disease, and to build a vigorous, aggressive store force trained in health habits must be a vital part of the management, a force co-ordinated with employment, education, engineering, and selling. The human machines are the most complicated machines in the store to keep running. To select, to fit in, to adjust, and to improve these men and women in the store organism is the real function of mercantile hygiene.

Abstract of Discussion

Dr. H. W. Stevens, Boston Mass.: The attempt to evaluate the physical capacity of workers has apparently not attained the certainty of result for which we have hoped. Physical examination has been proclaimed as

Chart I. Comparative use of nine store health departments as of March, 1922, showing total population, total visits to health department, new cases, and revisiting.

the cornerstone of all intelligent medical work. Contrasted with the slipshod clinical methods which most of us have at some time observed, the simple information to be obtained by gross examination without laboratory facilities or other refinements is of incomparable value. Those of us, however, who have made and observed the practical results of examinations of large groups, in spite of some striking individual benefits, have grown progressively disappointed. To many of us, I suppose this disquieting suspicion came first during the crisis of pressing need for military effectives. A classical illustration of this fact is found in our war experience with cardiac disability, nowhere better presented than in Dr. Thomas Lewis' little book "The Effort Syndrome and the Soldier's Heart." The theme of this book is in substance that much is to be found in the way of symptoms traditionally charged to heart disease without demonstrable heart defect; and that there is also considerable demonstrable cardiac defect without disabling symptoms. The logical conclusion, which has stood the test of practical experience, is that *performance in the final criterion of disability*.

The experience of industry also seems to be leading us toward some such conclusion, for the admission seems inevitable that the determination of gross anatomical defects or even of physiological deficiencies does not effectively grade men from the viewpoint of industrial efficiency. Dr. Roger Lee in a recent paper discussing physical examination of Harvard students says "in many ways the results of physical examinations in industry have been disappointing—the results of physical examinations do not seem at present to be stated in terms that enable us to appraise the personnel as exactly as the material assets of industry can be appraised." There seems at least a very strong presumption that it is not the defect alone that disables a man but what he thinks about the disabling effect of his particular physical ailment. "Industrial disability," which, as I take it, in its simplest terms means failure to perform on account of physical impairment, is at present a confusing complex of actual physical defect, together with many other factors, social, economic, psychic, arising from the man's industrial relations. We are all familiar with individual cases in which we have been morally certain of simple failure to accomplish masquerading as physical disability.

To furnish absolute proof of this is

often difficult. Our records, however, show some suggestive figures—those relating to illness "lefts" and "returns." We have prepared charts presenting the numbers of illness "lefts" and "returns" in the Jordan-Marsh Company over two corresponding periods at opposite seasons of the year. The "return" curves show conspicuous oscillations with peaks corresponding to the first working day of the week. The number of returns on the last three days of the week are relatively insignificant. The "left" curves show less conspicuous depressions falling fairly regularly on the second working day. From all we know of disease incidence and recovery there is little reason to believe that there is a cyclic fluctuation with a seven day period in the restoration of physical condition to working efficiency. It is probable that a searching physical examination to determine fitness to resume work would reveal no such result as the "return" curve on our chart. "Beginning the week right" is a common remark among returning absentees. "Tuesday begins my pay week" is very common. The generous benefits of a Mutual Aid Association doubtless are a factor.

#### Need for Precise Standards

A relatively brief experience with industrial workers is productive of numerous other equally striking phenomena less capable of graphic representation. The "functional nervous" classification mentioned by Dr. Emmons is one of these. Thus far we have done little toward the analysis of this group, although at present these complaints represent one of our most expensive losses. In fact we even suspect that the larger portion of our illness disability falls in this class and is not to be demonstrated by ordinary physical examination.

The sum of our observations to the present points to the urgent need of physical standards more precise in their reference to physical fact, also embodying something that our present gross standards lack, and at the same time translatable into language that industry can understand and apply to its processes of production and merchandising.

I fear we are prone to become "highbrow" in our attempts to adapt our medical knowledge to actual health needs. In our work in Boston we are doing our best to keep our feet upon the earth and at the same time to keep at least one eye upon the stars. We are working at present with clumsy tools but are looking forward to a more practical method of

grouping morbidity facts—a classification to be evolved only through the accumulation of widespread experience in practical needs. Such a classification, we believe, will be one that shall present each diagnosis as a physical fact which in itself shall point in one direction to a definite meaning in terms of physical impairment and in the other to an assignable cause with which it shall be the task of prevention to cope.

The opportunity for community service is one of which we know too little. About two years ago I began my venture in industrial work with a brilliant vision of the possibilities. Those of us whose lot is the daily routine know now that community hygiene in the full sense in which we conceive it is still but a fair ideal. In the direction of its fulfillment, however, we can see certain fairly definite tasks to be accomplished. There is before us much patient give and take in coordinating our efforts with those of the private physician, hospital, and other agencies. There are years of adjustment in which we must wrestle with fundamental questions of the ethics and economics of medicine in the communities. Much more must be learned about the real causes of impaired health and disabilities before the preventive measures of our ideals can be formulated and applied.

#### America's Medical Dean

Dr. Stephen Smith of Montour Falls, N. Y., who at the age of one hundred years has again been honored by his Alma Mater, Columbia University conferred upon him at its 168th commencement the honorary degree of Doctor of Science. Dr. Smith was the founder of the American Public Health Association and later served as its president.

# Heart Disease in Industry—Border Line Cases

## The Hope of Prevention Lies in Early Recognition and Complete Adjustment to Cardiac Difficulties

BY CADIS PHIPPS, M.D., ASSOCIATE PROFESSOR OF MEDICINE, TUFTS MEDICAL SCHOOL, BOSTON, MASS.

**D**URING a recent study of the different diseases and conditions causing incapacity in workmen as shown by the cases examined for the Massachusetts Industrial Accident Board, as the impartial physician appointed under the Act, I found that more than one-third of these showed either definite disease of the heart or some derangement in its functioning sufficient to cause symptoms. These figures, of course, do not apply generally. The type of case reaching the impartial physician is, in the first place, incapacitated, and second, there is some question as to the diagnosis, or prognosis, or causal relationship to the occupation. However, heart disease is a far too common condition, playing perhaps as serious a part now in our public health as tuberculosis. There are approximately 150,000 deaths yearly due to heart disease in this country and although we have no extensive statistics, it would seem fair to estimate that 2 per cent of all adults have definite heart trouble, if we may judge from the number of rejections because of this condition in the Army and among applicants for life insurance.

Because heart disease may be distinctly benefited by proper treatment, either by relief of symptoms, by prevention of increase in its severity, or at least by making this increase less rapid, it is obvious that not only should all cases be under supervision, but also that they should be recognized as such at the earliest possible moment. The question naturally arises, then, as to what means we possess for this early recognition and treatment. In the first place, we may institute routine physical examinations of all men seeking employment. This, however, not only fails to solve the problem, but is open to certain criticisms. The usual routine physical examination is not understandingly made and in it the stress is apt to be placed upon the more obvious lesions—although they may be of small import—and so cause the rejection of a healthy, capable workman because of a comparatively harmless murmur or functional irregularity. Furthermore, such examinations are prone to overlook the obscure or borderline cases. Granting that an em-

*The examining physician who is alert for early signs will discover many borderline cardiac cases amenable to treatment. It is especially important in this group to observe the patient as well as the disease, removing all causes of undue stress, whether physical or psychic.*

*The individual reaction of the patient is to be determined, and his activities planned well within the limit of the heart's ability. It is not the obviously damaged heart that suffers from neglect so much as the obscure, borderline case.*

ployee receives a routine examination at stated intervals, it is quite possible that cardiac disease may manifest itself in the interim.

It is of importance, therefore, not to depend on routine examinations, but to have some means of recognizing cardiac difficulty as soon after its onset as possible. As a means of doing this, industrial physicians should investigate all illnesses or incapacities with a clear understanding of what symptoms suggest cardiac difficulty. The diagnosis of a severe "cold" or bronchitis may perhaps, on investigation, prove to be some degree of cardiac decompensation with resulting cough, expectoration, and dyspnea. The statement that the employee's feet have been "bothering" him may depend upon the edema of a failing heart. "Gas," a common lay diagnosis, may in reality prove to be abdominal enlargement due again to heart disease. "Rheumatism" or "neuritis," involving the left chest and arm, may be the pain from sclerotic coronary arteries, or, more commonly, the complaint of "indigestion," with a history of attacks of epigastric discomfort, when occurring after middle age, should always suggest angina pectoris.

Besides the investigation of such symptoms and incapacities, the time-sheets and efficiency records of modern manufacturing plants will often be of suggestive value. Hand in hand with the loss of heart power goes usu-

ally a corresponding loss of working ability, nor is this surprising when we consider how dependent are our activities upon the circulatory system to meet varying conditions. The suspicion that some cardiac lesion may exist in an employee calls for a careful physical examination, bearing in mind that many cases may be so obscure as to pass unnoticed unless all the means at our disposal are employed.

Not only may initial cardiac lesions be difficult of recognition, as mitral or aortic endocarditis which may show little more than a roughened sound, but also some of the other lesions may be slight in degree, or, because of the cardiac reserve, may be overlooked, particularly if the patient is not exercised so as to throw strain on the heart's action. Auricular fibrillation may be demonstrated often by observing the different pressures registered by the individual beats during a blood pressure estimation, as will pulse alternation; fatty or fibrous degeneration of the myocardium may, in the absence of other lesions, such as a fibrillation, be demonstrable only after exertion. Heart-block, if slight, may require instrumental means for diagnosis. The recognition of coronary sclerosis will almost always depend upon a careful history of the patient's symptoms. One of the most obvious and common conditions—simple arrhythmia, with premature contractions—is apt to be misleading; usually functional and dependent on nerve disturbance, it is distressing and alarming to the patient and, if purely functional, will be decreased in degree by exercise.

It is of interest to note that the two commonest conditions, mitral regurgitation—forming 40 per cent of my cases of heart disease occurring in industry—and the simple arrhythmias—forming 15 per cent—are the lesions usually most easy of recognition, but relatively the least harmful, as 72 per cent of the cases of mitral regurgitation were not incapacitated because of their heart condition and practically all the cases of simple arrhythmia with premature contractions would be benefited by exercise.

Apart from the question of what heart lesions may be perhaps difficult of recognition, or where there may be

a question of the degree of impairment, there is still the large group of borderline cases, where the heart's ability to perform its duties under working conditions, and the prognosis of the lesion, is to be passed upon. There are certain diseases, such as aortitis and heart-block, which will tend to become worse because of an underlying disease, even if the heart be rested as much as possible. Under the best therapeutic conditions mitral stenosis tends to increase in degree with increasing damage to the heart muscle in most instances. Other heart lesions may suddenly cause death from an acute dilatation following exercise, or, as in a case of coronary sclerosis, emotional as well as physical stress may prove fatal.

### Tests of Cardiac Power

However, of more importance than the mere diagnosis of a specific lesion is the determination of the heart's ability to do its work, and what its reserve power is, and it is to this end that much of our attention should be directed. Many methods of determining this have been devised: different exercises, with a comparison of pulse rate, blood pressure, intensity of the murmur, size of the heart, etc., before and after the exertion. Vital capacity of the lungs has been used in conjunction with these. No one of them, and no one group of them, is suited to every individual case. The muscles which are particularly fitted to do certain work because of long training will perform their duties with less exhaustion and less wear and tear on the heart than would be the case if untrained, poorly developed muscles were called upon. The Army test of cardiac power, consisting of hopping on one foot, will mean less exertion and less dyspnea and rise in pulse rate to the toe-dancer than to the blacksmith and, conversely, the lifting of a twenty pound weight ten times above the head will not prove an accurate criterion of judgment of the degree of cardiac injury in the blacksmith.

To obtain the best idea of the heart's condition, particularly keeping in mind that what we wish to get is not a name of some lesion, but rather the amount of work which the heart can do without injuring itself, we must combine most of these methods of functional examination and correlate them with the symptoms as obtained in the history, as well as the patient's general physical condition. It is an advantage, also, particularly in planning for the future of the patient,

to test out the effect on his heart of such muscular exertion as would be needed to carry on his own vocation.

If, thus, we have been able to pick out those employees who have some degree of heart damage, and if we may, as suggested above, form some estimate of what may be expected of them under their usual working conditions, two duties fall upon us. In the first place—the easier problem to attack—we must protect the industry. For economic reasons, we should not allow men to attempt to fill positions for which they are unfitted because of some heart lesion: they should not be allowed to do poor work, nor should they undermine their health in attempting to do good work. They should be refused work which overtaxes their heart's strength. Opportunity for sudden or violent exertion—or perhaps extreme emotional stress, in some cases—should be removed, and the employee should be warned of such danger. Our second duty, to the employee, must consist in trying to relieve his cardiac condition in so far as possible, and this entails arranging his work with the idea of giving him *less* than his heart is able to do without injury. This may mean lighter work, work of a different kind, or perhaps complete rest. Of great importance in the recognition and perhaps the prevention of the borderline case is a knowledge of what conditions enter into its production. The specific diseases—rheumatism, syphilis, diphtheria, scarlet fever, hyperthyroidism—are common causes of heart trouble, and so should be treated with this fact in mind. Arteriosclerosis and chronic Bright's disease, with or without arterial hypertension, almost always have some harmful effect upon the heart, and so in selecting work for such patients, the increasing cardiac embarrassment must be taken into consideration. Certain poisons, such as lead and arsenic, may play at least a part in the production of heart disease, and, besides our prophylactic measures, this fact would suggest more frequent and careful examinations of workmen engaged in their manufacture.

### Exercise Often Beneficial

It is obvious that the heart cannot be rested completely as can other muscles of the body; it must continue to work that the individual may live. We may relieve the heart of some of its work, however, by complete physical or bodily rest. This should be done for all acute or decompensated cases, and should be of sufficiently long duration. Complete physical rest

is the common treatment advised for the obviously pathological heart. Sometimes, however, it not only is unnecessary, but it may occasionally be of distinct harm to the patient. It is well established medically that certain of the arrhythmias rest upon a distinctly neurotic basis and that the more apprehensive the patient becomes from noticing the condition, the more marked the condition tends to grow, thus forming a "vicious circle." To label such a patient as "cardiac" and to advise his giving up all work involving exertion, as is often done, is distinctly harmful, because it tends to make him introspective; such a heart would not be in any way injured by vigorous exercise, and the confidence the patient would gain on perceiving the absence of ill effects from exertion would go far towards relieving his condition.

Besides such purely functional disturbances, very many of the cases of heart disease will obtain benefit from some degree of exercise. An injured limb must be rested at first, but after a time the curative process will be hastened if we begin to use this limb. In treating the injured heart, therefore, there should be allowed an ample period of complete rest (in my experience, this period is usually far too brief) but which should be followed by a gradual return to working activity, never reaching the stage where the work has an injurious effect upon the heart, as evidenced by the tests described above.

### Conclusion

It is not the obviously damaged heart which is neglected; it is the obscure, or borderline, case. A borderline case is oftentimes more amenable to treatment than the established or long-continued lesion, and so may be benefited if recognized. To determine if an obscure heart lesion be present, it is usually not sufficient to depend upon a routine physical examination; a careful history of the symptoms and a consideration of various etiological factors, combined with several physical tests, must be employed.

Besides protecting the industry, the employee's health must be of prime interest. His interests are best served (in regard to cardiac disease) by (1) removal or preventive treatment of possible causes; (2) earliest possible recognition of cardiac disease, (3) complete rest for a sufficient period of time, followed by (4) a gradual return to working conditions, never reaching the limit of the heart's ability.

## Clinics for Industrial Workers

At a meeting of the Industrial Relations Committee of the Philadelphia Chamber of Commerce, with representatives from industrial, medical, and surgical organizations held recently, a plan was developed to establish modern medical clinics to handle ten thousand workers in Philadelphia whereby all employees of the industries in the city may have the same attention in cases of injury or illness as is possible in the establishments which maintain first class clinics of their own. It is estimated that with these clinics the expenditure of large sums now spent on compensation will be eliminated, that many lives will be saved, and that much in-

validism resulting from injury will be avoided.

## Eyesight Tests in Industry

Under the auspices of the Federated American Engineering Societies, an investigation to determine the extent of defective eyesight among children and industrial workers will be conducted throughout the United States, with the object of sight conservation. This investigation will be conducted by the Council on Eyesight Conservation with the assistance of local health and educational officers. The Council has reported that only one-third of the twenty-four million school children receive adequate tests of vision.

The newly elected directors are: Dr. L. G. Harney, St. Louis, Ill.; Dr. P. K. Brown, San Francisco, Cal.; Dr. C. D. Selby, Toledo, O.; Dr. Harry A. Mock, Chicago, Ill.; Dr. Wade Wright, Boston, Mass.; and Dr. T. R. Crowder, Chicago, Ill.

## ANNUAL REPORT—SECRETARY—TREASURER, MAY 22, 1922

When the affairs of the Association were turned over to the present Secretary-Treasurer, June, 1921, there was a balance of cash on hand of \$639.78. Today, after a year unusual in many ways, there is a balance on hand of \$682.50. With the balance from the previous administration came some liabilities—bills for stenographic services at the last annual meeting and for the printing of the 1920 proceedings.

### RECEIPTS

Cash from previous administration.....	\$ 639.78
Dues and donations 1921-22.....	1,132.72
Total receipts .....	\$1,772.50
Cash in bank at end of fiscal year....	267.54
	\$1,504.96

### DISBURSEMENTS

leaving together with checks already received for this year's (1922-23) dues—a balance of \$682.50. This, however, is not the whole story. The bills unpaid, listed below amount to \$1,154.83.	
To NATION'S HEALTH for subscriptions .....	\$ 545.50
Stationery and membership campaign .....	45.39
Modern Hos. Pub. Co. for 1920 proceedings .....	563.94
	\$1,154.83

leaving a deficit of \$472.29.

In view of this fact and the need for more funds to carry on and extend the usefulness of the Association, the Board of Directors have voted that assessment of five dollars per member be asked for. If this is obtained from a sufficient number, and expenses of the Association are vigilantly guarded, another year should show a healthier condition of its finances.

Concerning the other affairs of the Secretary-Treasurer's office, a membership campaign was ordered by the Board of Directors last September which in due time was launched through appeals made to members to do what they could in securing desirable new members. From our own members and others, a list of some seven hundred names of physicians engaged in some form of industrial work was obtained, and from time to time invitations were extended to these men with the result that in a year when most individuals and concerns were not taking on new activities, eighty-three new members to date have been passed on by the Membership Committee, and the drive—if it may be considered such—is still bearing fruit, for a number of applications are under consideration. Others are in prospect, so that we should be able to report in a short time at least one hundred new members as a result of this effort to increase our membership.

During the year past twenty-nine have resigned, so that to date we have 578 members as opposed to 499 of a year ago. The cost of this campaign was \$97.31, approximately \$0.13 plus per prospect.

What has been accomplished during the past year may be summarized as follows:

- (1) We have increased our membership.
- (2) We have reduced the number of delinquent in their dues, from 162 as of last June to 62 as of May 1 this year.
- (3) We have spent less on salary for the Assistant Secretary (reduced from \$75 monthly to \$25 monthly).
- (4) We have given the members more for their money than they have ever had before—and chief in this has been the issuing bi-monthly, through the cooperation of the Conference Board of Physicians in Industry abstracts of industrial medical literature. Generally speaking, these abstracts have met with approval and appreciation. To date we have sent out eight issues of the abstracts and reports at a cost of nine cents plus per member.

On the whole the affairs of the Association are in a healthy state and the future is promising and this opportunity is taken to thank everyone for his splendid cooperation towards the Secretary's office. The ground work is laid for active and effectual work during the coming year. We bespeak your cooperation.

## ASSOCIATION LETTER

BY WILLIAM ALFRED SAWYER, SECRETARY

THE Seventh Annual Meeting of the American Association of Industrial Physicians and Surgeons, held in St. Louis May 22-23 has passed into history. It was well attended. One hundred and two registered. Many dropped in for individual papers who did not register. The number who registered is approximately one-sixth of the membership—a very remarkable showing. If the membership of the American Medical Association attended its annual meetings in such numbers it would be difficult for any city to accommodate its conferences. This bespeaks a genuine interest on the part of our membership and augurs well for the future. The papers together with a digest of the discussions will appear in successive issues of THE NATION'S HEALTH.

At the Annual Meeting held in Boston in 1921 it was recommended that the name of the Association be changed and shortened to "American Association of Physicians in Industry." This was put into the form of a proposed amendment to the constitution and presented to the annual meeting in St. Louis, where it was promptly voted down so that the name of the association remains the same as it has always been.

From time to time the question of increasing the membership dues in order to care better for the expenses of the Association has been brought up, and it was revived again this year.

The meeting could not increase the dues at this time as it necessitates changing the constitution and by-laws but it did the next best thing—levied an assessment of five dollars per member for the current year. You will hear more of this later. The financial affairs of the Association have been in a somewhat precarious state for some time and to enable us to get clear of certain obligations and adequately care for secretarial and other expenses, this assessment was made. It is hoped the membership will respond readily.

After much discussion by the Board of Directors and by a Committee appointed to consider the Association's future policy in regard to an official journal, it was decided in open meeting to discontinue relationship with any journal at the termination of the present arrangement and, beginning January 1st, give our Publication Committee free rein in placing our material where it may reach its largest audience and do the most good. This, in view of the larger interest and opportunity ahead, seems wise for the present.

The following officers and directors were elected for the ensuing year: Dr. C. E. Ford, New York City, president; Dr. Loyal A. Shoudy, Bethlehem, Pa., first vice-president; Dr. Donald B. Lowe, Akron, O., second vice-president; and Dr. Wm. Alfred Sawyer, Rochester, N. Y., secretary-treasurer.

# Canada Restores Her Cripples

INVARIABLELY when the subject of the war veterans disability problem comes up, the statement is made that this country might have learned much from the work carried on in Canada. In response to a request for detailed information on the subject, Mr. E. H. Scammell, Assistant Deputy Minister of the Department of Soldiers' Civil Re-establishment, sent a writer for the *New York Times* a summary of the activities of the Canadian Government in connection with the demobilization and re-establishment of members of the expeditionary forces up to December 31, 1921.

One thing must be borne in mind in comparing the work of the United States with Canada, that is, the disparity in numbers. According to the report 595,441 men was the total of Canada's army. Of these 418,052 proceeded overseas. Our numbers were many times that. In the same manner the disability problem of Canada was but a fraction of ours in size. Due credit must, however, be given to the Dominion. Of a total of 51,708 disabled veterans who began training prior to the end of last year, 41,912 have graduated.

Prior to the Great War it had never been considered necessary to provide vocational training for men who were disabled by war. Apart from the payment of a small pension these men were allowed to fend for themselves and often drifted into the ranks of the unemployable. The Government of Canada was the first of the allied Governments to recognize that the re-training of the disabled men at public expense as a definite and necessary post-war problem. A commission was authorized to provide facilities for such retraining and for the issue of pay and allowances while it was in progress. Arrangements were made for the opening of special schools, for the utilization of existing provincial and private institutions and for the placement of men in industry where an intensive apprenticeship to the new trade could be carried out. As an adjunct a special employment and follow-up service was established. Large numbers of disabled men availed themselves of these facilities, the peak of the load being reached in March, 1920, when upward of 26,000 were undergoing training as stated above. The total who commenced training prior to Dec. 31, 1921, was 51,708, of whom 41,912 had gradu-

ated. Of the balance, 634 at that date were undergoing training and 9,162 had discontinued their courses for various reasons. These men were trained in 421 separate industries. Follow-up statistics showed that 65.6 per cent were subsequently employed in the work in which they were trained.

## Two Policies

At the commencement of the vocational training work two policies were open to the Government:

(1) To take the men and train them in highly skilled trades such as carpentry, printing, plumbing, machinists, etc., which without previous skill in these trades to build upon would have taken from one to three years or possibly more.

(2) (a) If they were skilled in some occupation to build upon that foundation by training in some lighter occupation closely allied to it where former experience might be made use of, or (b) If there was no previous skill to build upon, to train in some occupation, not piecework, where a full going wage could be earned in from six to eight months.

The second method has been adopted as a general principle. Herein lies the strength of the work in Canada, the limitation of the period of training at the end of which a man is sent out to a job. It should be noted that those who received training in age from youths to men of fifty years, in education from the illiterate to the university student, industrially from the lowest grade laborer to the highly skilled mechanic.

An extension of the vocational training privileges was granted in April, 1919, by which those who enlisted under the military age of eighteen years might be trained in industry or in a technical school, college, university, business college or one of the department's training classes. It was realized that a large number of these young men, had it not been for war service, would have become skilled workmen and self-supporting, but that the years they spent in the army had, in many instances proved a severe interruption to their training. It appeared very undesirable to force these men into the ranks of unskilled labor. The number who commenced courses up to the end of last year was 11,587. Of this number, 3,247 discontinued their courses, twenty-nine were still in training at

that date and 8,311 had graduated.

To more fully re-establish the men and make them totally independent of outside aid, a law was passed in November, 1919, authorizing the re-establishment department to make loans to certain classes of former members of the forces. The following is the authority which was granted:

That the Department of Soldiers' Civil Re-Establishment at its discretion be authorized to advance by way of loan to those disabled men who have been retrained and who are in need of same, a sum not exceeding \$500 for the purchase of tools and equipment necessary to establish them in their new occupation, such loans to be repayable within five years from date of issue without interest.

That the Department of Soldiers' Civil Re-Establishment at its discretion be authorized to advance by way of loan to those men who are disabled and who are in need of same, a sum not exceeding \$500 to enable them to pursue any course of training or education that was substantially interrupted by war service, providing in all cases that the disability was of such nature as to make assistance necessary and provided further that such men are not entitled to or have not taken training under the Department of Soldiers' Civil Re-Establishment; all such loans to be repayable in five years without interest.

## Disabilities Recognized

In order to carry out this authority a special division of the Vocational Branch was created and loan officers were appointed in the various units. Before the granting of a loan careful inquiry is made into the reasons advanced and into the prospects of successful operation. A chattel mortgage, where possible, is secured and arrangements are made for repayment in small amounts. Up to the close of last year 1,801 applications for loans had been approved. The number of different occupations in which men have been re-established under this scheme is 86. In such occupations as plumbing, cabinet making, carpentry, etc., the actual tools required by the journeyman are purchased to enable him to obtain employment at the prevailing rates.

It was early recognized that not only was it necessary to provide medical treatment and training for a returned soldier but that he should be introduced to employment when in a fit condition to work.

As far back as October, 1915, the secretary of the Military Hospitals Commission was directed to prepare

a report on the subject of the provision of employment for members of the Canadian Expeditionary Force on their return to Canada and the re-education of those unable to follow their previous occupations because of disabilities. It was pointed out in this report that all those who returned would be found in one of the following classes:

(1) Able-bodied men for whom the situations and positions they left have been kept open by patriotic employers.

(2) Able-bodied men who were out of work at the time of enlistment or who have been superceded in their absence; and invalided and wounded men similarly situated who will become able-bodied after a period of rest in a convalescent home.

(3) Invalided and wounded men who are unable to follow their previous occupation by reason of their disability but who will be capable after proper training to take up other work.

(4) Men who are permanently disabled and will be unable to earn their own living under any circumstances.

A scheme was outlined for close co-operation between the Federal and provincial governments which resulted in a conference between the Military Hospitals Commission and the various provincial governments being called by the Prime Minister in October, 1915. At that conference an agreement was reached for the creation of provincial returned soldier employment commissions. All the provinces took up this work and each commission was regarded as a sub-committee of the Military Hospitals Commission. The provincial commissions came into direct contact with the returned soldier, his wishes, his causes for complaint, etc., and the officers of these commissions were able to interpret to the soldiers the desires and policies of the Government. They were also instrumental in introducing a large number of men to employment.

#### Seven Hundred Weekly

With regard to the vocationally trained or disabled men, the department still maintains a special section and its activities have been most successful in finding suitable openings. To the 31st of December, 1921, out of 49,621 applicants 27,885 have been placed, 8,558 are on a waiting list and the balance have withdrawn their names. Notwithstanding the present unemployment situation, the number placed weekly seldom falls below seven hundred. All applicants for employment through this section are graded and special preference is given

to those most seriously injured. Close co-operation exists between the department and the Civil Service Commission. Between March 1 and Dec. 31, 1921, 970 handicapped or disabled men were placed in the permanent Civil Service.

Special preference in respect of vacancies in the Civil Service was made an act of Parliament before the armistice. These preferences at once gave the returned man an absolute lien on all positions for which he could qualify. The returned man was not slow to avail himself of the opportunity and vacancies in every class of employment have fallen to him. Not only was this preference accorded by law but the Civil Service Commission utilized every possible means of bringing to the attention of the returned man the opportunities offered him.

That this policy has proved beneficial is clear. Up to December 31, 33,719 men have been appointed by

the Civil Service Commission. Of these 10,121 are filling permanent positions.

Together with vocational training, loans and civil service employment, the Canadian Government also offered the returned soldier the opportunity of becoming a land owner. An act was passed in 1917 creating the Soldier Settlement Board and empowering this body to make loans to soldiers who wanted to engage in agricultural work.

There are other ways in which the Canadian Government has aided the returned soldier, pensions, unemployment help, medical treatment, etc., but the plan which has succeeded in rehabilitating him is the broad one which includes vocational training, loans, civil service and farms. Not the least important feature which has made for the success of the movement is the close follow-up work between rehabilitation and employment.

## Must Study Chronic Disease

THERE is need for wider specialization on the more common organic diseases and for centers of research so that chronic conditions may receive the careful attention and benefit from the precise methods of attack which are employed in acute conditions. Lee K. Frankel of the Metropolitan Life Insurance Company is quoted by the *New York Times* as saying: The spread of health education, in which the Metropolitan Life Insurance Company has taken an active part since 1909, has been a strong factor in reducing death rates from acute conditions, as have nursing services, and increasingly effective health laws.

The same improvement will mark the more fatal chronicities only when these disorders receive the attention they deserve and become the subject of research. When the people realize that disease commonly believed to be incurable can be reduced toward the vanishing point, as typhoid has been reduced, they will demand that more hospitals be devoted to the treatment and study of organic diseases, and that a greater percentage of physicians and surgeons specialize in the care of these ailments.

Four of the most important organic diseases continue to show a higher mortality than during the early months of 1921. These diseases are cancer, cerebral hemorrhage, chronic nephritis and organic heart disease. The increase for each is small, with the exception of heart disease, the

year-to-date rate of which, 150.3 per 100,000 persons, is much higher than for the same period last year, which was 133.3.

The cancer rate is 72.2, as compared with 68.8 for the same period in 1921; the nephritis rate is 77.6, as compared with 74.2, and the cerebral hemorrhage rate for the first months of this year is 67.2, as compared with 65.1 for the same months last year. The death rate for tuberculosis shows a gratifying decrease this year, but this disease still ranks high among the mortality causes. The rate for the first ten weeks of 1922 is 109.0, as compared with 123.1 for this period last year.

The mortality statistics of the period 1911 to 1921 show that these organic diseases, with the exception of cancer, declined consistently, but by no means as sharply as some of the more popularly dreaded diseases. For cancer the trend of the death rate has been upward rather than downward. Consider typhoid, for instance. It seems to be rapidly approaching the vanishing point as a cause of death. Its mortality rate per 100,000 persons among our policy holders for 1911 was 22.8, while in 1921 it had shrunk to 6.6. Influenza and pneumonia combined showed a remarkable decrease as a cause of death in this ten-year period. The rate per 100,000 persons was 131.2 in 1911 and 75.1 in 1921. In cases where medical aid was general and adequate there has been a great saving of lives, there having been 55,000 fewer deaths among our policy holders in 1921 than if the 1911 mortality rate had prevailed. But all the health measures have not reduced the almost steady high death rates for organic diseases to the degree that they have reduced those for acute diseases.

# INSTITUTIONAL HEALTH

*The Health Problems of Schools and Colleges, Hotels, Summer Camps, Children's Homes and Homes for Dependents*

## Purdue's Great Student Recreation Center

LARGE enough to accommodate all the needs of the students, yet designed so that it will not stand out more prominently than the other structures on the campus, the new Purdue Union Memorial Building with its basement and two stories promises to be one of the most ideal of its kind in the country. It will be made of brick of a combined color of red and grey trimmed in Bedford stone, the entire scheme blending with the slate roof.

The ratification in February of the plans for the building marked the culmination of two years of work on the part of the Union Committee, combined with the previous knowledge of the architects, Pond & Pond of Chicago, gained in the planning of other Union buildings, notably the Michigan Union.

In designing the building, every need of the student body was taken into account. Before any actual architectural work was done, a survey was made of the needs, both material and social, of the present student body, these results being multiplied by the fractional increase in enrollment for the next ten years. A body of five thousand students, including seven hundred women, formed a correct basis for computation, it was thought. Statistics were compiled recording the number of students fed at each meal at restaurants and boarding clubs in Lafayette, the number who visited confectioneries each day, and the number who took advantage of recreational facilities offered. An estimate was made of the probable number of campus activity meetings which would probably be taking place simultaneously, the attendance at each being considered.

The building has been divided into two wings, the first of which will be built immediately with the total funds

available at the time of its completion, while the second will not be added until more money is obtained. Provision has been made for future additions and enlargements in case proposed space is inadequate.

Carefully calculated estimates place the cost of the shell of the first unit at twenty-seven cents a cubic foot, or \$401,000, which, of course, will not include fixtures costing approximately an equal amount. The ultimate cost of the first wing will be about \$750,000, while the building completed with both units will reach approximately \$1,250,000.

The main entrance which is surmounted by a tower leads to the Great Hall and concourse on the first floor. Great Hall, the memorial part of the building, is two stories high giving

the effect of the tower. Here will be placed tablets to the memory of Purdue men who served in the war and to those who lost their lives in the service of their country. To the left of Great Hall is the concourse, a general lounging room, from which both the street and the interior of the campus may be seen. On this floor are also included the men's lounging or smoking room and the assembly room, a place which will seat five hundred at a banquet or accommodate three hundred and fifty couples at a dance.

In the basement is the cafeteria which will ordinarily accommodate eight hundred, serving three times each meal and about a thousand at peak loads. The billiard room will contain about ten tables and the bar-

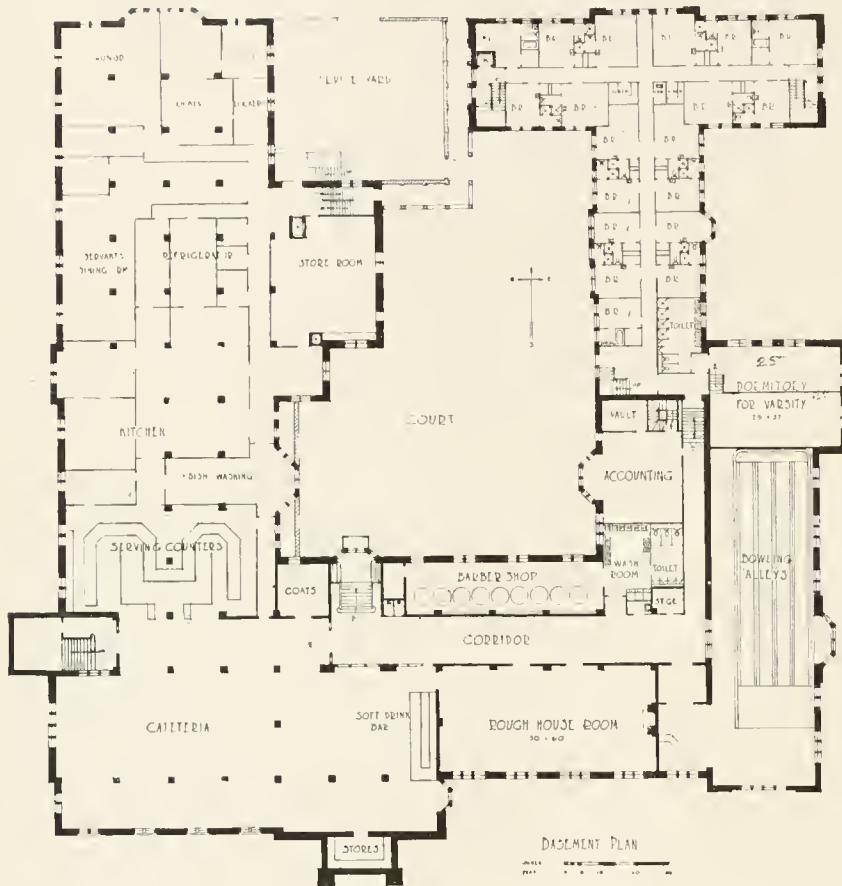

Front and side view of the Purdue Memorial Union building which, when completed, will house the student activities of the University.

men and women, and to provide accommodations for educational, scientific, and industrial conferences and meetings to the end that Purdue men and women may be brought in intimate touch with problems, leaders, and workers in a wide range of activities; all to the end that students, faculty, and alumni may have facilities and be surrounded by conditions and opportunities which tend toward the development of a broader culture, initiative, a democratic spirit, generous rivalry and a zealous love of Alma Mater; all of which purposes and activities shall be educational in character and are intended solely to supplement the education furnished by the University as prescribed in the curriculum."

The Purdue Union was organized by the class of 1912. By 1914, \$71,000 had been raised. The fund continued to grow with the coming of each class until the outbreak of the war in 1917. Four thousand and six Purdue men and women served in the war, sixty-three making the supreme sacrifice.

At the close of the war, the Union took on a broader scope and decided to raise funds for the erection of an activity building as a memorial to those men who served and those who

ber shop nine chairs. At times other than meal hours a soft drink stand will be operated in the cafeteria, thus making it continually useful.

On the second floor there will be the women's lounge room, private dining rooms, a large dining and conference room, and space for accommodating all campus activity offices.

A tower room over the main entrance will be used for committees, possibly as a faculty club room, or for whatever else is deemed advisable at the time of completion. It is hoped that the first wing of the building will be completed by January, 1923.

The second or right wing of the structure will contain hotel accommodations for University visitors and alumni, bowling alleys, visiting Varsity dormitories, and an augmented billiard room. There will also be included what is called a "rough house" room in which students may gather to do as they please.

The Purdue Memorial Union was organized with the following purposes set forth in the constitution: "The purposes of the Purdue Memorial Union are to organize the activities of the undergraduates, alumni and faculty; to furnish a social, recreational, and educational center for the Purdue

On the first floor is Great Hall, the memorial hall of the building, the lounging rooms and the assembly where large banquets and dances can be held.

Hotel accommodations will be the main feature of the right wing of the second floor.

lost their lives in the war. At the end of that year \$800,000 had been pledged.

J. E. Walters, President of the Purdue Union makes the following statement regarding the Memorial Union:

"The Purdue Memorial Union was originally the Student Union. It was started by students and carried on by them up to the war. Under many difficulties they continued the work during the war with the main purpose of bettering the student life through activities and getting a building

which would facilitate all the activities. After the war the program took on a broader scope and included a memorial plan which would do honor of a just kind to those who lost their lives and those who served their country during the war.

"Every effort was put forth by the students to make the University 100 per cent Purdue Union members. The results were that 85 per cent of the students are now life members with only 40 per cent of the alumni life members."

## Conference of Social Work

THE forty-ninth annual meeting of the National Conference of Social Work was held at Providence, R. I., June 23-29. Robert W. Kelso in his presidential address on "Changing Fundamentals in Social Work" touched briefly on the main problems dealt with in the division meetings,—health, mental hygiene, the treatment of delinquents, industrial problems, community organization, etc. The change of ideals in all these fields is toward the recognition of the spiritual value of the indi-

vidual, he pointed out, and to the acceptance of the philosophy of responsibility of the community to the individual as well as the individual to the community. The recommendations of a committee in 1912 on "The Standards of Living and Labor" were reviewed by Owen R. Lovejoy, chairman, and compared with present achievements. The problems have not been solved, but a public conscience toward them is measurably developing and we are at least, he assured us, "headed forward to a day when a

nation can feed, clothe, and house itself without destroying any of its people or any other people in the process."

In the Divisions of Health and Mental Hygiene important papers were presented and discussions on health in relation to technical matters of social policy came up in several others. Mr. Kelso interpreted the change of ideals in public health to be one of departure from old negative enforcement of health regulations to the present policy of requiring an individual to guard his health as a citizen and as a protection to his neighbor.

Dr. George E. Vincent, speaking on "Underlying Concepts in the World Movement for Health," called attention to the present working agreements among nations in regard to quarantine, purification of drugs, exchange of information about research and administrative problems; and he emphasized the human tendency to get out of focus through absorbing interest in special problems. To correct this we must devise public health measures that are economically possible.

Both in the sessions of the Conference itself and of its kindred groups there was evidence of a growing professional consciousness and a desire on the part of social workers more definitely to determine their professional status. There was evidenced a greater simplicity, courage, and frankness in discussing achievements and standards than has always been apparent in the past; and in the several divisions a timely emphasis was placed on qualifications and training for social work. The American Association of Social Workers, one of the kindred groups, voted to establish professional requirements for membership, and the fifteen hundred members present pledged twelve thousand dollars to meet the present deficit and as a declaration of their ability to finance their organization independently of outside contributions. There are few things of greater importance to the future of social work in this country than the development of a group financially and professionally independent. The Association made definite strides toward establishing such a group by declaring its intention and ability to finance its budget, by limiting its membership to those having professional training and experience, and by ruling out the ancient and unhappy distinction between paid and volunteer workers.

Homer Folks of New York was elected president. The Jubilee Meeting will be held in Washington, D. C.

# Facilities for Prenatal Care in Chicago

## Summary of a Survey Made by the Chicago Community Trust

By FRANK D. LOOMIS, SECRETARY, THE CHICAGO COMMUNITY TRUST, CHICAGO, ILL.

WHAT facilities has Chicago for the care of the sick and disabled? Are the facilities adequate? Are they up-to-date? Are they efficient? The person called upon to contribute might at times complain that Chicago has too many hospitals. Patients seeking hospital care, especially hospital care at a price within the means of the salary-earning group, have frequently been distressed because there was no room. Physicians have criticised the lack of facilities for proper care of particular types of patients. Managers of hospitals have been hopeful for the future, believing that Chicago is rapidly becoming a great medical center with institutions the best to be found anywhere.

A group of prominent physicians two years ago suggested that the Community Trust undertake a survey of the institutional facilities for care of the sick and disabled in Chicago, believing that such a study would bring to light many facts not generally known about the facilities which do actually now exist and would help to bring about improvements and coordinations which would really make Chicago the great medical center which many have hoped it would be.

A preliminary study of the situation made it apparent, however, that a general and sweeping study of the entire field at one time would be impracticable. It seemed preferable, rather, to take up from time to time such special subjects as conditions might warrant—subjects which might seem to be ripe for investigation and to offer some hope for definite results.

The subject of prenatal care in Chicago was the first decided upon, because of its importance and because little is generally known about it. A survey, directed by Mrs. Kenneth F. Rich, with the assistance of Miss Ella F. Allen, R.N., and the advice of a Committee of specialists including Dr. Joseph B. DeLee, Miss Edna Foley, Dr. James B. Herrick, and Dr. R. W. Holmes, has now been completed and published in pamphlet form. The report consists of 102 pages, and is doubtless the most complete and thorough study which has been made on

this subject in any American city. It shows that Chicago has some institutional facilities for prenatal care of good quality, but rather meager in amount. It also makes clear that much is yet to be done in standardization and unification, in the special training of physicians and nurses and the development of an understanding public sentiment which will demand good service, before Chicago can be said to have arrived at the consummation of any well-rounded community plan. Chicago is far behind New York, and America is considerably behind European countries in the prevention of maternal mortality.

### High Mortality Preventable

The report calls attention to some statistics of the United States Government which show that in this country as a whole more women of child-bearing age lose their lives from diseases caused by pregnancy and confinement than from any other disease or class of diseases except tuberculosis. When the statistics are compared with those for Chicago the same relative prevalence of maternal mortality seems to exist, for in the latest year for which records of the Board of Health are available (1914) it was found that tuberculosis among women of child-bearing age was first, and maternal mortality was second.

The next significant fact is that a great deal of infant mortality is due to causes connected with birth. Official statistics for the U. S. Registration Area in 1919 indicated that 43 per cent of all the deaths of babies under one year of age were from causes related to the natal and prenatal periods. The United States Public Health Service states that one hundred thousand babies in this country die in the first month of life, most of them because of conditions affecting the mother before the baby was born. In Chicago it is stated that 1,428 babies died in 1919 before they reached the age of one year because of "congenital debility and malformations" and that this is 24.8 per cent of all the babies under one year of age who died in Chicago. In that year, this being the second highest of all the causes of death of babies.

Evidence is presented to show that a large percentage of these many deaths of mothers and babies is preventable. This is proved from the statements of leading physicians who have made extensive study of the subject and from the records of prenatal dispensaries or clinics such as are now established in some parts of Chicago and in other cities. It is shown that among the mothers who attend these clinics there is a remarkably low death rate both of mothers and babies. In view of this fact, it is sad to discover that in recent years there has been no general decrease over the country as a whole from deaths due to natal or prenatal causes, although there has been marked improvement in some spots. An accurate statement regarding Chicago is impossible, owing to the inadequate registration of births and deaths, but the figures which are available indicate slight improvement.

The character, quality, and quantity of prenatal center work in Chicago have been carefully studied. The survey found twenty-eight centers or stations in active operation. A considerable group of these is located on the west side near the County Hospital and there is another large group on the south side in the vicinity of Twenty-sixth street east of State Street. The other centers are scattered north and south, north as far as Fullerton Avenue and south as far as East Fifty-first Street. Since the clinics naturally draw most of their patients from their immediate vicinities, it follows that large areas of the city have no institutional prenatal service. The striking discovery in this connection was that in these neglected areas maternal and infant death rates are highest. All of the clinics combined serve a total of not more than 6,000 patients a year, or scarcely more than 10 per cent of the 57,000 cases in the city. The patients are generally those "unable to pay ordinary physician's fees." Seven of the clinics are connected with medical schools and are not supposed to be run solely for the benefit of the patients. In some cases, it is intimated, the service seems to be influenced too largely by this consideration; or the

rooms and equipment provided for the prenatal clinics are sacrificed to other interests of a hospital. Prenatal service, as a standardized and distinct service, is rather new in Chicago, however; most of the clinics having been organized or developed since 1910, and there have been many recent improvements. Nineteen of the prenatal centers have social service departments; and all but three have nurses regularly in attendance with usually one or more graduate nurses who perform a variety of services.

The thoroughness of the service rendered at the various clinics was carefully analyzed. At each of 16 institutions, fifty recent consecutive records selected at random were studied, and the number of patients' visits to the clinic, the number of months under care, and the thoroughness and regularity of medical examinations and instructions were noted. Seven institutions furnished a smaller number of records than 50; while the remainder of 28 institutions (5) furnished none. In the number of patients' visits one institution showed an average number of 4.2 and there were four others which showed an average above 3. The average length of time under care ranged from less than one month up to three months. In number and regularity of urinalyses, one institution showed a grade of 97.2 per cent; there were four which graded above 90 per cent; or six above 80 per cent. In the number and regularity of blood-pressure tests one institution had a perfect record; 4 graded above 90 per cent; 6 above 80 per cent.

The manner and efficiency with which records are kept occasioned some criticism. The adoption of a uniform record blank is suggested, with the recommendation that whatever system is used, it should be regularly followed.

#### Low Cost for Each Patient

The subject of finances is discussed under the general title, "Fees, Funds and Costs." Under "Costs" it is stated that in Boston, when prenatal care began, the cost was found to be between \$2.50 and \$3.00 per patient; while in New York it has been demonstrated that prenatal supervision can be carried on at an approximate cost of \$2.40 per month for each mother supervised when the work is done entirely by nurses; or \$3.50 per month if physicians are employed. This cost included the salary of the doctor and nurse, as well as all overhead. The Infant Welfare Society of Chicago has found that prenatal work, introduced

as an addition to an established infant welfare station, costs less than a thousand dollars a year for each clinic. The larger Chicago clinics minister to 300 or more women a year. The cost of prenatal work of most Chicago stations is not figured separately from other dispensary or hospital costs. It has been estimated, however, that the average cost per patient's unit in Chicago's general dispensaries varies from 11 cents in institutions in which costs of heat, light, rent, etc., were not included, to 78 cents in the case of one Chicago dispensary with all such expenses included. "It must be borne in mind, however," the report states, "that practically all of the medical service in dispensaries is given free of charge by the attending physicians."

There is no general policy or practice with regard to payment of fees. Some institutions make no charge whatever; some charge 10 cents to cover cost of registration; some make a flat rate of 25 cents to cover both admission and prescription fee; some request patients to pay fees approximating the cost of private service. Often there is a charge for medicines or for special tests, which when made, are usually on the basis of actual cost, but sometimes higher. It is quite common, however, to waive the fee if the patient cannot pay.

The survey recommends that an effort be made to standardize these fees and the following considerations are mentioned: "First, all the institutions are in need of additional income for the purpose of improving the services; second, the majority of wage-earners are able to pay part of the cost for skilled medical service; and third, there exists a class of patients, chronic invalids and the unemployed, who will be deprived of treatment altogether if the admission fee is demanded in every case."

The subject of pay clinics, operated on a self-supporting basis, is alluded to; but the difficulties of maintaining such clinics without seeming to compete with private practice are not to be overlooked. The recent establishment in New York City of the "Dollar Clinic," by Cornell University College of Medicine which aims "to cooperate, not to compete, with the general practitioner" is cited.

The report concludes, in the matter of finances, that much of the support of institutional prenatal work must continue to come from public or private philanthropic sources, and says that the "unnecessary deaths of mothers and babies at child-birth present a most appealing opening for

private philanthropy." The establishment of clinics; the improvement of quarters; larger equipment; more doctors, nurses and social workers; or the endowment of chairs of obstetrics in medical schools and of maternity hospitals with free beds and modern teaching facilities are among the specific suggestions offered. The value of these for experimental and demonstration purposes is considered great.

The amount and character of prenatal care furnished to the 51,000 cases each year which do not come within the service of the institutional stations is not discussed at length because there is no means of determining its extent or quality. Reference is made to the 1920 report of the Health Department of Chicago, which states that of 55,313 births reported that year, 39,468 were attended by private physicians; 15,816 by midwives; and 29 were unattended. The 6,000 or less mothers given prenatal care in the clinics are doubtless included for the most part in the number reported by physicians.

#### Recommendations of Report

The survey report closes with two general recommendations:

I. That prenatal care be extended to all prospective mothers whom at present it does not reach, by: (1) Education of the public to the perils of childbirth, and their easy avoidance through proper foresight and care; such methods as proved effective in the campaign against tuberculosis being used; magazines, the press, pulpit, paid public lectures, propaganda by health officials, and personal contacts of home visitors; (2) a direct educational campaign among the physicians, through a series of papers on prenatal care and obstetric subjects, in medical circles; (3) persuasion of the hospitals to insist upon adequate prenatal care of all patients enrolling on their books for future confinement, as well as recommendations for establishment of more clinics, with better equipment and staffs.

II. That the prenatal care afforded by Chicago's agencies and institutions be coordinated and standardized through a permanent prenatal or maternity council, to consist of obstetricians, pediatricians, social service workers, nurses and other public-spirited citizens—a council which shall give consideration to the following phases of the program: (1) A comprehensive "Chicago Plan" for the location of prenatal centers; (2) the prevention of duplication and overlapping of effort through such systems as complete registration with the two

social service clearing houses, and by trial agreements as to districts or types of cases; (3) the maintenance of continuity of individual maternity care, through its antenatal, delivery, and postnatal stages, by a closer co-

operation among all physicians, hospitals, clinics and other institutions involved; and other subjects relating to the improvement of the service of the various prenatal centers.

A schedule of standards which may

be regarded as a minimum requirement for prenatal work, drafted by a local committee of physicians and nurses, is presented for discussion and possible adoption by all persons or groups concerned in this field.

# Air Conditioning in Hospital Sanitation

## An Application of Principles of Ventilation to Hospital Practice

By W. DWIGHT PIERCE, PH.D., MANAGING DIRECTOR, BIOLOGICAL DEPARTMENT, THE MINERAL, METAL, AND BY-PRODUCTS COMPANY, SAN MATEO, CAL.

ONE of the first steps made in the science of sanitation was in the direction of air-conditioning when the demand for pure fresh air became insistent. Through other incentives entirely there has arisen a science of air-conditioning which can give much of value to sanitary and medical science, and we will do well to consider what has been accomplished, what underlies the whole science, and how especially it can be applied in the field of health.

In general, we have known that air overcharged with carbon dioxide is unhealthy, and rules have been laid down specifying the maximum volume of carbon dioxide permissible in public buildings. But the student of air-conditioning now assures us that the capacity of the air to absorb carbon dioxide or any other gas and its danger to human health depends entirely upon the varying factors of temperature, atmospheric pressure, and relative humidity. This fact was especially brought out in the report of the Departmental Committee on Humidity and Ventilation in Cotton Weaving Sheds (Cd. 4484, London, 1909). This report was necessitated by a desire to obtain satisfactory weaving conditions, without too greatly affecting the health of the labor, but its findings did not result in laying down any definite principles upon which a real science of air-conditioning could be built.

To the textile industry probably we owe the first serious efforts to control humidity in industrial establishments, as it was found that without sufficient atmospheric moisture static electricity interfered with the processes, the fibers were more liable to break, and the fabric was not uniform. In fact, two very responsible engineering corporations have built up a large business through the development of systems of air-conditioning, including ventilation, air-washing, humidifying,

*To the textile industry belongs the credit for the first serious efforts to control humidity in industrial establishments. Experiments have shown that each worker has an optimum temperature or practicotatum in which he works with the most comfort and efficiency.*

*The application of these principles to the hospital cannot help but be beneficial. The problem of conditioning the air for the various diseases, maintaining a temperature least suited to the growth of bacilli and most suitable to the recovery of the patient is one which might well be considered by hospital authorities.*

dehumidifying, warming, cooling, and drying. These systems are the gradual outgrowth of the demands of the textile industry and later other industries of many kinds attained more suitable air conditions for their particular processes. These corporations have by individual plant studies worked out to the satisfaction of their clientele apparatus whereby the various plants have been able to improve the quality of their product, in appearance, or strength, or in some other manner, and much credit is due to them for their pioneer work.

But the field of air-conditioning is broader and more vital than accepted by even these pioneers. It opens up visions of greater industrial health, greater personal efficiency, and possibly a new principle of hospitalization. It is in the effort to bring these new ideas to the medical and sanitary professions that the present article was prepared.

Expressing the basic principles in terms of the sanitarian and practi-

tioner, we may set down a number of theorems which appear to be fairly well grounded at the present time.

(1) The normal physiological functioning of the body requires fresh air, or air not overcharged with carbon dioxide, or any other injurious gas.

(2) Modern industrial practice makes it possible to secure fresh air, or air made fresh by washing, and to maintain it at whatever combination of conditions may be specified by thermostatic and hydrostatic automatic control.

(3) The quantity of carbon dioxide which may be held in suspension in the air with safety to the worker, depends upon the factors of temperature, relative humidity, and atmospheric pressure.

(4) The reactions of temperature upon living organisms can only be correctly thought of in terms of humid-temperature.

(5) At a given temperature the capacity of the air to absorb moisture depends upon atmospheric pressure.

(6) For every living creature, plant or animal, no matter how low in the scale of development it may be, there is a zone of humid-temperatures in which the life functions of metabolism, assimilation, transpiration, growth and reproduction, are at their greatest efficiency. This applies to every cell and organ of every creature, and to every function of the organism. By greatest efficiency we do not necessarily mean capability to do the greatest amount of work, but rather the capability to do the greatest amount of accurate, dependable work, with the least exhaustion, wear and tear. This zone of temperature and relative humidity is what we used to call the optimum, but was renamed the practicotatum by the writer. The practicotatum for man is a zone, more or less elliptical in form if charted on paper, having approximately as its ultimate boundaries 32 and 55 per

cent humidity, and 55° and 70° F. temperature. This zone was denominated by Rosenau, as the comfort zone, for within it we are the least conscious of the existence of air conditions, and feel the greatest sensation of personal comfort.

(7) The factory, school, hospital, office building, church or auditorium equipped with modern air-conditioning apparatus that will maintain throughout the year a fixed condition within this human practicotatum will, needless to say, maintain the conditions most favorable to health, happiness, contentment, and human efficiency. With proper measures for reduction of gases and dusts such conditions are almost ideal. It is no longer an imaginary condition, but an actual reality, and so accurate that by thermostatic and hygrostatic control temperature is held within two degrees and humidity within four per cent by both the leading systems of air-conditioning.

(8) Surrounding the practicotatum is a more or less large thermopractic zone, which in the case of man we may call the zone of practical working conditions, and for other living creatures we may call the zone of effective humid-temperatures. Broadly speaking no man should be expected to work, except for very short periods under factory conditions, at humid-temperatures outside of this zone, which may be roughly described as bounded by 36° and 90° F. and 2 per cent and 85 per cent humidity, with a diagonal axis running from 43° F. and 100 per cent humidity to 78° F. and 0 per cent humidity, elliptical in form with the short axis perpendicular at 63° F. and 43.5 per cent humidity. The curve of the ellipse is tangent upon but does not cross the line of the wet bulb of 70° at 30 inches pressure.

(9) Hospital patients should be kept by all means within this zone, for it is the zone of bodily activity, and how can we expect the healing processes to take place when the air conditions inhibit them? The nearer the patient can be kept to the practicotatum the better. Of course in this connection we must remember that the disease organism also has its practicotatum and our patient must be held under thermopractic conditions least effective for the disease and most effective for the recuperative processes in the patient's own body.

(10) Any condition of weather can be brought into any factory or hospital. Geography and climate have been conquered. If you want to do something which has always in the past been associated with a certain

place or climate, you can now do it at home by installing artificial weather. There is no reason for sending a patient to a distant climate, which may be exhausting and enervating and far out of the bounds of effective conditions, when in the hospital in his home town, near friends and the source of funds, he can be kept in a cheerier mood at the most favorable conditions for the curing of his malady.

(11) Surrounding the zone of practical working conditions are subzones of debilitation and discomfort, of sluggishness, of pain and intense suffering (either from cold, heat, dryness, or moisture). Work is often done under these conditions, but it cannot be satisfactorily done, and the health of the laborer is soon impaired. Any condition which causes a feeling of chill, a numbing, a thirsty or parched condition, excessive perspiration, stifling, depressing fatigue, frequent need of rest, quickened or sluggish pulse, or fever is dangerous to health, and lies within the boundaries of these subzones of debilitation, sluggishness, and pain. Under no circumstances should hospital patients be kept under such air conditions.

(12) Surrounding these subzones is the anesthetic zone or zone of unconsciousness, comprising all those conditions which induce sleep and unconsciousness preceding death. In the lower animals true anesthesia is displayed by the phenomena known as hibernation and aestivation which the writer has shown are one and the same phenomenon. For instance in dry countries, an insect may be in the anesthetic zone throughout summer, fall, winter, and in fact through several years, with extremes of hot and cold weather, and will only awaken when the necessary humidity brings the air conditions within the zone of effective humid-temperatures. With man the anesthetic zone is very dangerous but we see it in people who fall asleep in the cold (rhiganesthesia), or who collapse from thermoplegia or heat stroke, and are while unconscious in a state of thermanesthesia. The human death zone (olethric zone) is very close to the anesthetic zone and its position depends largely upon the individual's physical condition.

(13) A temperature which is thermopractic at one humidity (that is 90° F. at 35 per cent humidity) may be thermonochelic—causing sluggishness—at another humidity (90° F. at 65 per cent humidity), thermalgesic causing pain and fever at another humidity, (90° F. at 80 per cent humidity), and thermanesthetic, ther-

moplegic or thermolethric, at a still different humidity (witness strokes and death at 90° F. and 100 per cent humidity).

(14) Although 90° F. and 100 per cent humidity brings about stroke and death, such a condition at 5 per cent humidity is not likely below 115° F.

(15) Although 70 per cent humidity is regarded as the best for weaving we must not think that any temperature can be withstood at this humidity, for stroke and death may occur at 70 per cent above 105°; at 100° only cautious work is possible, because of rapid rise in body temperature; at 90° hard work is impossible; and in fact operatives should not be required to work above 82°; at 79° one feels discomfort and perspiration; but below 75° there is little or no discomfort in ordinary clothing; at 65° to 70° the best weaving is done in England; at 60° English weavers are satisfied; at 50° to 57° best work is done in New England; below 37° a sense of chilliness is experienced; below 28° one is sluggish; below 22° pain and frost bite are experienced; and below 10° there is danger of freezing to death unless very active, warmly dressed, and well nourished.

### Good Air Increases Health

There is no doubt but that any industry adopting this modern theory of air-conditioning and installing an appropriate system therefor will greatly increase the efficiency and health of its workers, as well as better the quality of its products. Bread made by the new system of air-conditioning is superior in quality, and the same may be said of macaroni, candies, chemicals and drugs, rubber, and chewing gum, and multitudes of other products. Needless to say foods made under sanitary air conditions will be superior also from the sanitary standpoint.

It is not the province of this article to speak of the relative merits of the commercial systems in use, but the purchaser can expect satisfaction if he receives a guarantee that the system when installed will meet his specifications. He should specify an air-conditioning system that will enable him to control both humidity and temperature automatically in any room or throughout the plant, at any fixed combination he shall desire; that the system shall be so flexible that the conditions in any room may be set at will by adjusting the automatic controls; that he may maintain different air conditions in different departments at the same time. In the rainy

season the humidity is too high outside and the dehumidifier must rectify this in the plant. In the dry season the humidifier will carry the burden. In the cold weather the heating system, and in the hot weather the refrigerating system will function. In other words the true air-conditioning system has at least four functions—heating, cooling, drying, moistening and to these may be added air-washing and ventilating.

Just what combinations of temperature and humidity are necessary in any department to obtain the best quality and greatest quantity of this quality of product, with the greatest efficiency of machinery and at the least strain upon the physique of the labor, is a question which must be determined by independent investigation in each department of a plant. In the human factor alone we must consider the racial reactions of the employees, the previous environment, the health and the clothing of the individuals. Just as by psychological tests we ascertain the relative fitness of applicants for particular tasks, by thermopractic tests we must ascertain under what conditions the acceptable candidates are most fit and must endeavor to place them at their tasks under such conditions as to derive the greatest amount of efficiency from them.

Finally, without in any way desiring to express an affirmative opinion for or against any present-day system of hospital practice, the writer desires to set to thinking upon certain definite points those who are in better position to know.

(1) Presuming that fresh air is desirable, especially for patients with bronchial and lung diseases, is it true that any kind of fresh air is equally efficient? Arguing merely from personal behavior, the writer feels that raw cold air, supercharged with moisture, and hot stifling air, similarly charged, and intensely hot still dry air may be so depressing that the tissues have no chance to mend. Would not fresh vitalized air of moderate temperature and low humidity be the most desirable in the case of such diseases?

(2) Is it not possible that in fever cases a rapid change of air to give fresh oxygen and remove fever affluvia, maintained at a moderate moist temperature would give better results than uncontrolled air? Or at least, is it not possible that by controlling the air you could find conditions superior to the average uncontrolled hospital conditions?

(3) Would not dehumidification be

of great aid in moist weather in the treatment of rheumatic and asthmatic patients?

(4) Is it possible that in diseases with alternating chill and fever the patient's condition might be ameliorated by a control in the opposite direction of the room conditions?

(5) In dealing with diseases characteristic of winter time would not fresh air conditions of summer time be of tremendous aid in hastening

control of the diseases?

(6) Does not a patient recuperate faster when the air conditions are most pleasant?

(7) Would the obnoxious hospital disinfectant gases be as necessary if the air was constantly being changed and fresh washed air of suitable temperature replacing it? Would not the absence of these odors be beneficial in the cure of many patients with hypersusceptibility of gases?

## A Plea for the Deaf Child

THE English law lays down that the hard-of-hearing child need not attend school until the age of seven. In Scotland deaf children must attend school from five years upwards. A better plan for the ultimate value of special training would be to attack the problem of the deaf child in the home, by the age of two, and every school for the deaf should carry an infant class for pupils from two and one-half to five years, states Macleod Yearsley in his recent "Plea for the Deaf Child," in the pages of *The Lancet*, for the usually deaf child's mind does not begin to develop until he enters school.

It is because the general faculties develop chiefly through and by speech that the deaf child suffers so great a handicap. By hearing the child obtains the faculty of speech, and thereby the language without which he cannot reason clearly. Neglected during the plastic stage of early childhood, he is retarded to a degree that often gets him classified with the mentally defective.

The acquisition of speech may be called the physiological education of the child for it is, indeed, a physiological process. In the normal child, in full possession of all his senses, this physiological education begins practically in the cradle. By means of his hearing he is storing up sensory impressions of speech during every minute of his waking life, and without these the motor mechanisms which produce speech cannot be developed. Only by beginning to educate the deaf child as early as possible can we hope to attain any semblance of automatization in speech. Plenty of bright, intelligent deaf children are now let loose to play in the streets, there wasting the precious early years that should be devoted to giving them the physiological preparation for later education that the hearing child gets without help.

Dr. Kerr Love, the Glasgow author-

ity, is responsible for the good conditions that obtain in Scotland in handling the deaf. He instituted the classes for the little children and has issued a pamphlet of help to mothers in the early training of these children. He considers that special information that will lead to the early detection of these handicapped children should be in the hands of parents, school officers, and especially of dispensary surgeons.

Dr. Yearsley makes a very strong plea for the children who become deaf at a later age from causes which are largely preventable. In these children special education should begin as soon as they are discovered and their deafness is known to be incurable. Otherwise as soon as they become deaf they rapidly lose such speech as they may have already developed. When this happens during the pre-school period, these children come into the same category as the young deaf child, and there may be the same difficulties in discovering him. More than one such case has been known to be sent off to a mentally defective school. To avoid such exigency, Yearsley suggests a simple hearing test which can be made by the teacher when the vision test is made.

Yearsley has fostered establishment in London of special hard-of-hearing classes or centers as a means of generalizing the special educating necessary and of reducing the heavy cost of such instruction. Five such centers are in full working order in various parts of London, all of them meeting with immediate success. They have been used, also, in some parts of the United States. In these hard-of-hearing centers the children pass one-third of their time under a certificated teacher of the deaf, who instructs them in lip-reading, and the remaining two-thirds at lessons in the hearing classes of the school to which the center is attached. In this way they obtain practice in lip-reading and

learn to combine it with what remains to them of hearing. Intelligent pupils make such progress that many of them can be returned to their own elementary schools after six or twelve months in the center.

According to Yearsley, timely interference can prevent a heavy percentage of the acquired deafness of children. He quotes Tomlinson, an American authority, to the effect that 80 to 90 per cent of all cases of acquired deafness in children are referable to disease of the middle ear; in 90 per cent of these the condition is due to extension of inflammation from the post-nasal space, and the most frequent cause of this inflammation is adenoids. A systematic examination of adenoid cases shows that three-fourths of them have some ear affection, and, lastly, the routine examination of the ear in children with ade-

noids confirms the belief that many of the cases of middle-ear deafness in early adult life originated in childhood in this manner.

Plenty of work is being done on the subject of prevention of deafness, and stores of knowledge are being accumulated; what is now wanted is the spread of this knowledge, so that the public, instead of looking for some heaven sent miracle to restore the hearing sense once lost, will instead devote the necessary attention to the discovery of any possible "residual hearing" that may be made the basis of the necessary physiological education. Especially pitiful are the victims of charlatanism, whose credulity causes them to suspend the processes of education proved by long and practical experience to be the only means of preventing mental deterioration in the deaf.

and children referred to the Jewish Aid Society and the Bureau of Personal Service and other similar agencies. This camp is free and is conducted by the Council of Jewish Women who furnish the cost of the entire camp. Five hundred women and children attended the camp from June till September. Daily outings were also arranged. Altogether 2,487 boys and girls enjoyed directed and supervised outdoor vacation privileges.

Over 2,000 men, women, boys and girls registered in the gymnasium classes of the Institute during the year. A physical examination was given to every member upon entrance and participation in classwork was made a requisite to playing in games or on teams. The girls maintained a successful basketball team; baseball games are arranged for the men; swimming classes are provided for both men and women.

A working girls' camp at Loon Lake, Antioch, Ill., about 50 miles from Chicago, offers a vacation to approximately 500 school and working girls. The camp accommodates one hundred at a time for a two weeks' period at a cost not to exceed \$1.00 a day for the working girl and little over 50 cents a day for the school girl. The camp has a bathing beach with a frontage of 500 feet; the ground occupied is 500x13,000x600 feet, all enclosed with a fence. There are 22 permanent cabins accommodating approximately six girls in 16 cabins and two each in six. A recreational hall for dances and entertainments is equipped with dressing rooms and stage, as well as offices for the nurse and director of the camp. A permanent kitchen and mess hall and proper facilities for washing are also included. The cost of the camp was \$25,000.

The Marion National Sanatorium, formerly the Soldiers' Home, National Military Home, Indiana, is being converted into a sanatorium for disabled veterans of the World War suffering from mental or nervous diseases. Eight hundred patients are now receiving treatment and when changes are completed there will be room for 150 additional men. The sanatorium maintains its own farm, laundry, postoffice, theatre, water works, ice plant, and heating plant. Recreation in the form of supervised athletics and occupational therapy is provided for the men. The staff includes twenty-three physicians, sixty graduate nurses, eleven educational aids, fifteen teachers, and other operative employees.

## A Jewish Community Center

A JEWISH Community Center which is serving to acclimate the old-world Jew to America's second largest city is the Chicago Hebrew Institute of which Philip L. Seman is director. In his annual report ending May 1, 1921 Mr. Seman gives much interesting data concerning the Jewish immigrant, his problems and his progress in the land of his adoption.

One of the most startling facts found was that of those who registered for the classes in English 60 per cent were graduates of a gymnasium, college, or university in their native countries. The classes contain Jews from twenty-three countries in Europe and Asia, the largest number coming from Poland, the next from Russia.

From the recreation standpoint, the children's game room located in the basement of the Institute at 1258 Taylor Street is most successful, having had an average daily attendance of one hundred children. Charts on the walls supplied by the National Child Welfare Association and the American Social Hygiene Association emphasize the need of health habits.

Equally popular have been the outdoor playgrounds which are open from 9 a. m. to 10 p. m. daily. The attendance during May, June, July, August, and September, 1921 was 300,225.

Gardening, practised on a small scale, is this year being turned over still more to the children and the entire work of digging, planting, hoe-

ing the gardens as well as harvesting the crop has given to the immigrant children crowded in the city their first inkling of the field of agriculture.

The Institute also maintains summer camps, one for boys at Long Lake, Ill., one for girls at Camp Summit Lodge, Area, Ill., and one at Western Springs for mothers and children. Camp Wilson, the boys' camp, is conducted in connection with the Young Men's Associated Jewish Charities which supplies the camp equipment and all other expenses. The Institute provides doctors' examinations. Three hundred fifty boys between the ages of 12 and 18 took advantage of the two weeks vacation the camp offered. A small fee is charged, \$3.50 for two weeks or \$2.00 for one, although this is not collected if the boy is unable to pay.

The girls' camp is not so fortunately situated, the personnel being limited to those recommended by the Home Finding Society, The Bureau of Social Service, The Dispensary, The Consumptive Relief Society, and similar agencies. Most of the girls had free fees, paid by the organization and those who did not, paid from \$3.00 to \$6.00 for the privilege. The director hopes that in the future the girls' camp will be placed on the same independent basis as the boys, open to any girl who wishes to take advantage of the outing. A total of 175 girls, 35 in each group making five groups, attended the camp.

The camp at Western Springs offers a two weeks' vacation to mothers

# Rochester, N. Y., Fights for the Children

## A Tonsil and Adenoid Clinic Which Has Brought Health to Ten Thousand

BY JOHN E. WEBBER, EASTMAN KODAK COMPANY, ROCHESTER, N. Y.

**A** TONSIL and adenoid drive in Rochester, N. Y., extending over a period of fifteen weeks and closing with a record of 7,883 operations performed on children under sixteen years of age sets a new standard in organized community effort for improved health conditions. In child welfare activity it is probably unique.

The Rochester Dental Dispensary, the gift of George Eastman, president of the Eastman Kodak Company, built and equipped at a cost of half a million and endowed for nearly two million more, is available to all school children up to sixteen years of age. Such are its far reaching results that the public tonsil clinic of this story was the direct outcome of conditions found in the routine examination of dispensary patients.

The dispensary was opened in October, 1917. The building is a beautiful structure, following simple architectural lines and containing all the most modern dental and hospital equipment.

The importance of a normal functioning condition in nose, throat and mouth is well known in dental science and in the organization of the dispensary an oral surgical department to care for cases not within the strict scope of dentistry was included. This department includes every facility for nose and throat work including the re-

moval of tonsils and adenoids and operations for cleft palate and hare lip, all of which are recognized as correctible conditions.

The original intention, however, was to operate only on such tonsil and adenoid cases as had a direct bearing

Breakfast at the emergency hospital the morning following the operation.

on dental development and plans were made accordingly. During the examination of dispensary cases however, many were found to have diseased tonsils which, although not strictly obstructive, were detrimental to the children's general health and which were being neglected by the families. Further inquiry showed the prevalence of this condition among children throughout the city with the number of cases constantly on the increase. The records of the dispensary confirmed by reports from the prophylactic squads working in the schools, by inspectors and nurses under the jurisdiction of the City Health Bureau, agents of various child welfare organizations, and from community nurses as well as the testimony of physicians and nurses, indicated that the number of operable cases had reached alarming proportions.

The causes of this accumulation were set down to the shortage of doc-

tors in private and hospital practice due to the war, the inability of hospitals and dispensaries since the war to overtake the accumulation, ignorance and indifference of parents both as to symptoms and ill effects of adenoids and diseased tonsils, and the financial inability of families of limited means to pay the fee of a regular practitioner. These conditions gave Mr. Eastman, the founder of the dispensary, grave concern. It was realized that unless the situation could be measurably improved, the regular dental work of the dispensary along preventive lines would be largely negative. The handicap of bad teeth had been removed but the equally deplorable handicap of adenoids and diseased tonsils remained.

Under these circumstances it was decided in the summer of 1920 to organize an emergency clinic at the dispensary. This clinic was the forerunner of the public drive which opened the following Spring. Fixing the quota of operations at forty daily, it was necessary to find dormitory accommodations for eighty patients—forty incoming and forty convalescing. By utilizing lecture rooms, library and trustees' rooms this cot accommodation was found. Children selected for operation were received at the dispensary between two and four o'clock of the afternoon of the day previous. Conveyance was provided.

An advanced case of adenoids discovered by the clinic.

The tonsil and adenoid drive in Rochester, N. Y., was the outcome of discoveries made at the dental clinic.

COMPLETE oral hygiene as practised by nurses and other attendants is not only recognized as good administration, but is a necessary precautionary measure adopted by medical directors, superintendents and superintendents of nurses in the safeguarding of patients.

Interest in sanitary, healthy mouths of hospital personnel grows steadily. The subject will receive even more attention in the future.

Colgate's Ribbon Dental Cream does all that a dentifrice can do in cleansing the teeth and maintaining oral hygiene.

New York, N. Y.

One of the ten thousand children who underwent a tonsillectomy.

The routine on arrival consisted of registering, bathing, supplying each child with nightgown, stockings and slippers. Their own clothing was folded in large paper sacks, which on the morning following the operation, were deposited by each owner's cot. Every child was also carefully weighed on arrival and thoroughly examined by the house physician and its condition carefully recorded. After a light supper the children were put to bed in the incoming dormitories and from then until 8:30 or 9 o'clock they were entertained with phonograph concerts and motion pictures.

Beginning at 8 o'clock the following morning they were taken in groups of ten to a waiting room and from there, individually, to the anesthetic room and then to the operating room. After the operation the patient was taken to the convalescing dormitories and there kept the remainder of the day and succeeding night under the care of the house physician and nurses. By 9 o'clock of the morning after the operation all, with the exception of the occasional child detained for observation, had breakfasted and were ready to return home.

A nominal fee of five dollars was charged but in no case was treatment refused through inability of families to pay. In this drive 1,470 children were operated upon between July 26 and September 10.

The complete success of this experiment immediately begot plans for a public clinic on a much more comprehensive scale. The larger project was undertaken by the four city hospitals with the cooperation of the public and parochial school authorities,

the City Health Bureau, and the Rochester Medical Association. In January plans were completed and the clinic opened to admit patients.

The annex of the main auditorium of the city was fitted up as an emergency hospital with a capacity of 180 beds and four operating tables, and was staffed by a supervising surgeon, a chief of medical staff, and twenty-seven graduate and undergraduate nurses. The physical examination of the children was conducted by a large staff of surgeons, physicians, and nose and throat specialists. The operations were, of course, performed by specialists. The routine followed closely the details of the dispensary clinic.

The quota of cases assigned to the public clinic was 80 per day or 400 cases a week of five days. In addition a quota of 200 cases a week was accepted jointly by the four city hospi-

tals and the dental dispensary. The clinic was financed by the Community Chest through the hospitals, the city paying the nominal fee of five dollars in cases where the family circumstances did not permit it.

A month prior to the opening of the clinic a survey of the school children was begun and two thousand cases listed ahead. These examinations were conducted under the direction of the clinic and the Board of Health, assisted by school nurses. Every child examined was classified. Those in need of operation were given cards setting forth their condition. These cards they took home for the signed consent of the parents to an operation. Appointment cards were then sent to parents.

Between these two emergency clinics, nearly 10,000 Rochester children have been given a better chance for health and mental development. Periodical examinations are also made to determine the exact value of the operation to the child. Examinations already made on children operated upon at the dispensary show remarkable results. Of the first group of 53 examined, improvement was noted in 50, eighteen of these showing great improvement. All of the fifty made gains in height, weight, and general physical condition. As an illustration, one girl showed a gain of 14 pounds, others of 11 and 10 pounds each. Among the boys one showed a gain of as much as 22 pounds, others of 15½, 14 and 11½ pounds.

The full value of this great experiment in public health none can foresee. To the medical profession it means a much needed opportunity for observation in large groups. To a world of mothers, however, its reassuring results will be watched with a very different interest.

### World's Largest Leper Colony

Underwood & Underwood. Five thousand and twenty lepers inhabit Culion, a little rocky island in the Philippines. They have a nipa shack village, and their municipal government is their own. They have a leper police force, a set of leper city officials and until recently they have been left largely to their own devices. The attention of General Wood has recently been brought to the condition of two hundred children in this community who, though born of leper parents, are themselves free from the disease. It was the original intention of the constabulary to establish a separate colony for them on Culion Island, but on the advice of the Rockefeller Foundation it was decided to convey them to Manila, where they will be placed in an orphanage until danger of the development of the disease has passed.

*A flexible shoe for your flexible foot*

Nature, in her wisdom, designed your foot arch to flex when you walk. Why restrain it in shoes that are rigid and without natural lines? "The foot is like a cantilever spring," wrote a noted doctor. "The Cantilever is the most comfortable shoe I have ever worn," said a trained nurse; and another woman said, "In Cantilever Shoes I feel as though I were flying."

every step. Cantilever Shoes make her feel as though she wore the wings of Mercury.

Though you may not be conscious of it, there are few things that spoil a good disposition quicker than shoes that nag you. Nerve strain, leading to backache, headache, and even to pains like those of rheumatism, may be caused by high heels and by shoes that bind and restrict the feet. Many writers on health and beauty subjects are now pointing out the importance of a woman's shoes in respect to her health, happiness, and personal attractiveness.

It is because of the *flexible shank* and *natural lines* of the Cantilever Shoe that you will derive such comfort from it. And because of its graceful appearance and its harmony with this Spring's shoe styles you will see it worn wherever daytime costumes are worn. Fine workmanship, splendid materials and reasonable prices add to make the Cantilever desirable.

You were given two marvelously constructed feet. At the nearest Cantilever Store, try on a pair of shoes suited to their needs. Keep your feet well and spare yourself the misery that has come to so many women. If wrongly designed shoes have already begun to injure your feet, a change to Cantilevers will help them. Weakened arches will be strengthened by proper exercise; your improved circulation will make you feel better and look better.

If none of the listed dealers is near you, write the manufacturers, Morse & Burt Co., 1 Carlton Avenue, Brooklyn, N. Y., for a nearby dealer's address and for the Cantilever Booklet, which tells some things you will be glad to know about your feet.

The graceful carriage and youthful walk of the Cantilever Woman are often admired. Her feet are free. She walks naturally, with a minimum of effort. Flexing with

# Role of the Follow-Up Nurse in Tuberculosis

## Right Social Contact with Patient Is Secured by the Follow-up Nurse

By MARY E. EDGECOMB, R.N., SUPERVISOR OF TUBERCULOSIS WORK, PROVIDENCE DISTRICT NURSING ASSOCIATION, PROVIDENCE, R. I.

IN considering the "follow-up nurse" in her relation to organized tuberculosis work, as we know her today, let us go back and think a little of her origin and development. In the *American Journal of Nursing* for June, 1901, Ruth Brewster Sherman writes as follows:

During the past few years large numbers of tuberculous persons have applied to the dispensaries of the Johns Hopkins hospital whose admission to the wards was obviously unwise and who after a single visit never returned and were lost sight of. To any thinking person those people poor, ill, and ignorant as they usually are, are objects not only of pity, but of very lively interest as being breeders and conveyors of our commonest infection, and each one the center of a veritable circle of danger in his own household and neighborhood, often indeed by reason of the necessity of still carrying on his occupation in spite of illness to people far outside his immediate vicinity.

To Dr. Osler, the medical chief of the hospital, the necessity for putting some limit on this danger seemed imperative and in 1900 he appointed from the third year class of the medical school a student whose duty it was to follow and visit in their homes all consumptives who came to the dispensary. Saturday afternoons, Sundays, and holidays were practically all the time she could give to the work, but the results of her months of efforts were most satisfactory. She had trouble in finding patients owing to fake addresses, especially with the Russians and Hebrews who were suspicious. She visited 199 patients in their homes, seeing them at their daily work, observing habits and surroundings, in each case instructing the invalids and their families regarding essential disinfection and limiting spread of disease. She found the consumptive in meat shops, small dairies, bakeries, cracker stores, sewing, weaving, cooking for sale, and cobbling. Bed-ridden invalids she found on couches in the living room. This year (1901) the work is undertaken with new courage and energy, and a student, also a woman, has begun visiting.

The student's work is of interest to nurses as being exactly what we ourselves might do and what we believe many nurses would be glad to do if the opportunity were given them. Such an opportunity of any definite nature exists nowhere at present, so far as we know, though undoubtedly the district or visiting nurses are able in the course of their general duties to perform a large amount of useful work in this direction.

This, however, cannot be compared in usefulness with the work which might be accomplished were it possible to make provisions for one or more nurses to carry on the special work regularly and systematically.

The three medical students who did this work were: Blanch N. Epler, Adelaide Dutcher, Elizabeth H. Blawvelt. The report by Dr. Dutcher was really what aroused enthusiasm in the home visiting of tuberculous patients.

The years 1902, 1903 and 1904 saw the beginning of such organized definite follow-up work by nurses and Grace Forman of New York, Reba Thalan and Nora Holman of Baltimore, and Elizabeth Upjohn of Boston stand out as pioneers in the field.

The description of the famous lung block in a report of the Committee on the Prevention of Tuberculosis of the Charity Organization of New York for the year 1902 stands out as a classic. It was one of the most congested wards in New York City. The report says: "The lung block alone holds nearly four thousand, not to mention dogs, cats, parrots, and one weakened old monkey. Of the humans, some four hundred are babies. It is a block packed close with high

grimy tenements, dark rooms lighted only by air shafts, consumptive patients doing home work." Case after case is cited where almost entire families were wiped out by tuberculosis. The report says: "In the past nine years alone this block has reported two hundred and sixty-five cases and this according to doctors, druggists, and others who know is but half the true number." It all reads like a tale of some eastern country, not a story of New York only twenty years ago.

In a measure these same conditions were found everywhere by the first nurses. Perhaps, not such congestion, not so many nationalities crowded in one block, but the same story of the desperately sick patient exposing an entire family, the same hopeless acceptance that tuberculosis was inherited, and entire families must die. The cry of the nurses was for milk, eggs, and hospital beds for the sick consumptive.

We have traveled a long way since that time. With the forming of the National Tuberculosis Association in 1904 began a definite campaign against tuberculosis, a campaign broad enough to include the building of hospitals and sanatoriums, the estab-

"No matter what our contact with the patient in the clinic, in the sanatorium, or in the office, we never know him or can intelligently advise him until we see him in his own environment and know for ourselves his family and grasp some of the things that have contributed to his breakdown."

## Metatarsalgia and Callouses Caused by Weakened Transverse Arch

This condition is recognized by depression of the Transverse Arch anteriorly or at the base of the Metatarsal bones. The dome-like arching is obliterated and painful callosities or corns form over the depressed Metatarsal heads. The foot broadens, the toes become dorsal flexed. Bunions appear at the First and Fifth Metatarso-Phalangeal articulations. Digital nerves become impinged and severe cramp-like pains are experienced through the toes. This is described by Whitman as Morton's Toe.

These conditions, Doctor, are quickly relieved and permanently corrected by the use of

### *Dr. Scholl's* *Corrective Foot Appliances*

These appliances are especially designed and constructed to restore the Anterior Arch, remove abnormal pressure and permit full freedom of motion to the entire foot. Different types to meet all emergencies.

Sold and fitted by leading shoe dealers in

every community who have been instructed in Anatomy of the foot and how to properly apply correctives to the foot and shoe.

Important pamphlet, "*Foot Weakness and Correction for the Physician*," mailed upon request.

ishment of fresh air schools, a campaign of education, and the follow-up nurse has had her definite place in that campaign.

#### Home Contact Is Cornerstone

The character of the work has slowly changed, has become more and more educational, but one thing stands out now as it has through the years—the contact with the patient in his home is the cornerstone in which all constructive tuberculosis nursing is built. No matter what our contact with the patient in the clinic, in the sanatorium, or in the office, we never know him or can intelligently advise him until we see him in his own environment and know for ourselves his family and grasp some of the things that have contributed to his breakdown.

There is the early case, the sanatorium case. Perhaps here we do our most satisfactory piece of follow-up work. First, we visit the homes after the diagnosis has been made either at the clinic or by the private physician. A patient who has just been told he has tuberculosis and must go to a sanatorium, no matter how tactfully this may have been done, is frightened and usually is willing to promise anything, but when he gets home and begins to think what it means to go away, he sometimes loses his courage, or fails to see how it is a possible thing because of family cares. Perhaps some neighbor comes in and tells him discouraging tales of the sanatorium or the advantages of some patent medicine. Then it is the nurse who is able to explain at greater

length what the clinic doctor has said, explain it in terms he and his family can understand. It is his salvation to be made to realize what tuberculosis is, and what the sanatorium has to offer him in the way of treatment and education. If he does not see it, then we must still follow for there is always a psychological moment in the life of an early case when he can be made to see if we are only there. We give him an accurate picture of life at the sanatorium so when he does go he will not come flying home because it is so different from what he has thought it would be. We can help him to make a plan for his family if necessary, advise him about his outfit so that when he gets there he will have what the others have. We are all dependent on custom and many a patient has been made unhappy when he arrived at a sanatorium because his outfit, while perfectly good, was irregular.

After getting our patient to the sanatorium, we must turn our efforts to the family. If he has been the bread-winner and he has a dependent family, then a definite plan must be worked out with the charity organization and this plan must include adequate relief. The family must be examined for no really constructive plan can be made unless we know the physical condition of everyone.

The nurse is the link between the home and the sanatorium and either by visit or letter must keep the connection between the patient in the sanatorium and the family at home. All of the time the patient is away we must be educating the family so that

when he comes home it will be to a family that knows all we can tell about sanatorium treatment, rest, fresh air and food, who will, therefore, be ready to understand and help, not a skeptical family unwilling to change in any way the routine of the home. When the patient comes home, an arrested case, we must still follow to see the kind of a job he gets, to see that he goes at regular intervals for examination to the clinic or doctor, to see that he does not work too hard, or play too hard and so lose any of the results of his valuable sanatorium treatment. We follow the suspicious case—no case needs us more—we gather all that is possible in the way of information to take back to the physician. It is not easy to diagnose tuberculosis, and patients in a doctor's office or in the clinic do not always give an accurate picture. The home setting and time are needed that we may get the history of old contact he has not realized, the clear picture perhaps of an old indefinite illness, typhoid or pneumonia, that lasted a long time, malaria or some other illness that was so labelled in his mind that he thought it had no bearing.

#### Social Value of Nurses' Work

On the other hand, we may find a social condition in the home that could explain symptoms that seem very like tuberculosis. If the social condition is adjusted and in the words of Dr. Emerson the patient is "free to gain," we may be of assistance to the medical man in making a diagnosis of "not tuberculosis."

We follow the advanced case. The advanced open case is a source of danger and should be in a hospital, but many times he does not go. Then we follow very carefully to give him the bed care he needs and to teach him to be the least possible danger to others, to teach the family how to protect itself.

This is no easy task. It takes many visits, a great deal of teaching to get a family to understand even the first principals of the cleanliness that means safety. While we care for the patient, it is really the family we are chiefly concerned with and perhaps it is in the long, patient following of these contact families that some of our best work is done, even if there is a negative examination for the entire family during the time of immediate contact. We, who follow families, know that the months or years following the death of the breadwinner are hard. The burden of financing a family falls on the mother or the death of the mother throws the care

## A comparison of Fleischmann's Yeast with the laboratory standard as concerns vitamin content

"As efficient as our very active laboratory yeast," said the scientist after the careful tests were completed.

The dotted lines show the normal growth rate of albino rats. The heavy lines show the growth rate of the rats when fed Fleischmann's Yeast.

SOME valuable vitamin studies have been recently made with Fleischmann's Yeast. The albino rat was the experimental animal used in a series of tests carried on over a period of three and a half months.

Altogether 99 rats, young and sleek, of from 60 to 80 grams, were used. They were given a standard diet from which only the vitamin-B was lacking. After a certain decline in weight due to lack of vitamin-B, Fleischmann's Yeast was added to their diet. The yeast was fed moist but on a dry weight basis. The rats always ate the yeast greedily. Their subsequent growth rate indicated the value of this yeast as a source of B-vitamin.

The chart with its caption tells the story.

Fleischmann's Yeast is a pure food

product, containing no drugs of any kind. It is a proven rich source of vitamin-B. Try it out on your own cases where vitamin-B is indicated. It may be eaten plain, suspended in water, milk or fruit-juices, or spread on crackers. The physician will regulate the amount of dosage which will probably vary with the individual needs. From one to three cakes a day has usually been found satisfactory.

Fresh yeast has therapeutic value entirely aside from its vitamin content. For full data on this interesting study, send for the recently published brochure on the manufacture, chemistry, physiology and therapy of yeast. This book is distributed free to physiological chemists, physicians and hospitals. Address THE FLEISCHMANN COMPANY, Dept. Y 7, 701 Washington Street, New York City.

of the children on the oldest girl and the family slips down. The resistance is lowered and infection flares up. The nurse who follows these families must have the social sense in that she must have some plan for the betterment of every family she follows. The influence of a nurse, an educated, trained woman, visiting a family sometimes for years, has a tremendous influence. In no other form of public health nursing work do we have quite this opportunity.

If we believe that adult disease is the result of childhood infection, then we should spend a great deal of time working with the children, teaching health habits, instructing parents about diet, following school children to see that the recommendations of the school doctor are followed. If fresh air schools exist, more intensive work is possible in a school where the health of the child is, perhaps, the first consideration.

The clinic is an important part of tuberculosis work and to be truly successful must be a happy combination of a good medical man who knows tuberculosis and who is interested in patients, and a good active nurse who is alive to the possibilities of a clinic. In the first place, it is the nurse who in a great measure feeds the clinics for it is the nurse going into the home who urges the contact case to go for examination from time to time. A contact case left to himself would never perhaps realize the importance of examination, certainly never the importance of re-examination if the first were negative.

The clinic itself offers many possibilities. While waiting for the doctor, we can get acquainted with the

new patient, let him feel the personal interest, and pave the way for the home visit we will probably make. We can talk to the old patients, sometimes the doctor is too busy to listen to all these troubles and it does them good to talk them over with the nurse who can pass on to the doctor in a word all that is of importance. After the patient has seen the doctor we can be perfectly sure he understands what has been told him, so that he knows how to use the sputum bottle and when to come back. All clinic cases must be followed to their homes to pass on to the family the word of the doctor, and much may be gathered from the family which is of value to the clinic doctor.

#### Difficulty of Reaching All

If we look over the death returns each week and visit every family where there has been a death from tuberculosis we open up a whole field of information. In no other way can we determine more accurately just what percentage of the tuberculosis cases are being cared for and the reasons why they have not been referred to us. It makes a good basis to work from. We realize that never will we have 100 per cent of all the cases perhaps for some of the following reasons: (1) Some patients have gone on and worked until almost the moment of death and have never gone to any doctor long enough for him to make or follow a diagnosis. With the growing industrial nursing work and the routine examination of employees it would seem as if this class of patients might be reached. (2) There are the patients who die in general hospitals with acute men-

ingitis or peritonitis, the children, and when these histories are taken we find many times there has been no known exposure, only history of acute illness in an apparently well child. These cases never will come to us. (3) There are the non-residents, who merely happen to be in the city when they die. (4) There is the transient, the lodger who rooms around, the man who, given an infection, his very mode of life makes it impossible to escape. We sometimes wonder how much the disease has helped to make him just the sort he is. If more were known about tuberculosis in its earlier stages such men would seek medical advice, and have a chance to get better, or at least have the hospital care that would mean food and shelter while they are in the more advanced stages. (5) There are the few cared for by the private duty nurse. (6) Then we find the family just waiting for us to come in, the badly exposed, contact family, the family with whom we do our best work.

In a study made in Providence an interesting fact stands out. A far greater number of the patients followed by nurses die in a sanatorium or hospital than those not followed. Of the patients who died at home known to the nurses 45 per cent had had sanatorium care at some time while of those unknown only 10 per cent had had any sanatorium treatment.

#### Follow-up Opportunities

Perhaps the follow up of men rejected in the draft turned over to the tuberculosis association to be followed will stand out as a national recognition of the value of follow up work. Many things were learned from it. It was unfortunate we did not get the names earlier so that every man could be located. In Providence only 79.6 per cent of the cases referred were located and I think these figures are not unlike those of other cities. The number of men with tuberculous hips and spines seemed large, but more significant was the fact that all of these men were more or less handicapped and only a very few had skilled trades. Their deformity dated back to childhood. With our more careful follow up work I trust we are offering more to our handicapped children today.

The Influenza gave us another opportunity to follow many families; 1½ per cent of the 1805 patients we visited were found to be definitely tuberculous; 3 per cent more were very suspicious, many of the suspicious cases have cleared up, some went on

Convalescent farms where patients discharged from sanatoriums may recuperate, are invaluable in the treatment of diseases requiring rest, graduated work, and fresh air.

**“With this Treatment  
I Seldom Write a Death Certificate  
FOR  
INFANTILE DIARRHEA”**

*THE BRITISH MEDICAL JOURNAL SAYS:*

“All experience goes to show that Virol is a food of marked value in a great variety of conditions in which adequate nutrition by ordinary means is not easy to secure, including the general range of diseases accompanied by wasting and summer diarrhoea.”

*“I have had most excellent results with Virol; in fact, to my mind it is the only treatment for infantile diarrhoea—barley water and Virol, or rice water and Virol. With this treatment I seldom write a death certificate for infantile diarrhoea.”*

Extract from doctor's letter.

## **DIET IN INFANTILE DIARRHEA**

To each half-pint of rice or barley water add one-quarter teaspoonful of Virol. Give one or two ounces of this mixture every two hours. In cases of great prostration add 10 to 15 minims of brandy. When the evacuations indicate that the infection is at an end, sterilized milk can be cautiously added to the Virolised rice or barley water, the milk being substituted for the rice or barley water, dram for dram, until Virolised milk is the sole article of diet. As the child improves the Virol can be gradually increased.

*A brochure on the treatment of acute summer diarrhoea  
will be sent to any medical man on application.*

# **VIROL**

*Used in more than 2,500 hospitals and infant clinics in Great Britain.*

*Sole Agents for U. S. A.*

**GEO. C. COOK & CO., Inc., 59 Bank Street, New York**

to positive diagnosis. In both draft and influenza surveys one appreciated what a routine examination would mean. We did not get so many new patients from these surveys but they did give us the opportunity to enter many homes and tell why we were there, and as much of tuberculosis as we could in a short time. We can only hope the educational value of our work was worth something although that, like much of our work, is of such indirect value that it is impossible to measure results only the years will tell.

To be a good follow-up nurse requires the best a nurse has to give—a nurse with a vision to see ahead of the work accomplished to the ideal she hopes for—a nurse who reads and studies, for what we know today about tuberculosis changes tomorrow or the day after, and the emphasis is laid today on this phase of the work, tomorrow or something else. She must know human nature for nowhere do we see more of all that makes up the character of a man than in the test of tuberculosis. She must know how to teach and teach simply that all may understand. Indications for 1921 are that the death rate will approach 100 per 100,000. In a few years it will be a disgrace to any community to have a death rate from tuberculosis of over 30 per 100,000, says the National Tuberculosis Association. That is setting a high and should spur us on to harder, better work than we have yet done. We are glad that we as public health nurses going into the homes of the people may have our share in what Dr. Lyman calls the "winning fight."

### Special Educational Needs of Children

Emphasis is placed by Dr. Sanger Brown, 2d, in the *New York State Journal of Medicine* on the psychological needs of school children, intellectual and nervous handicaps not being as readily appreciated as are physical defects. More than seven thousand children are taken yearly to the Children's Court in the city of New York on charges of disobedience, truancy, thieving, and vagrancy. Truant schools and probationary schools are inadequate and, while they provide special courses, satisfactory handling must include the determination of the clinical types to which these children belong, and curricula must be sufficiently flexible to be definitely prescribed if preventive measures are to be effectual with difficult children.

### James L. Fieser to Red Cross

James L. Fieser, recently appointed Vice Chairman of the Red Cross in charge of Domestic Operations was elevated to that position from the position of Manager of the Southwestern Division. Previous to that time, Mr. Fieser had been Associate Director of Civilian Relief at the Washington Headquarters. He began social work as Attendance Officer of the City of Indianapolis, went from there to the superintendency of the Associated Charities, Columbus, Ohio, and thence as director of the Cleveland Division of the Red Cross during the early part of the war.

### Physical Plants in School Medical Provision

The existence in the schools of London of a heavy percentage of children presenting more or less falling away from normal physical standards is emphasized editorially in *The Lancet* as an argument for improvements in school buildings—the classrooms, the public offices, and the playgrounds—the claim being urged that unsatisfactory surroundings have an important bearing in the production of and in unfavorable pressure upon constitutional defect. Certain it is that the physical plants of schools in themselves often constitute ordeals which the normal and tough subject may weather, but which may prove disastrous to less sturdy specimens of young humanity.

In this connection Dr. Addison considered as undesirable economy certain proposals to cut down by 20 per cent the grants to the School Medical Service, which would limit not only medical centers but would affect unfavorably the organizations for physical training and the serving of meals.

The discussion of matters marked for economy brought out the unjust-ability of many school buildings for their purpose. Cost what it will,

even in times demanding the utmost economy as to expenditure, it is hazardous and uncalled for to lay less stress upon the importance of lighting, ventilation, and furnishings for the premises of schools. The standards of sanitation and decency must be rigidly maintained. Where the health of the children demands structural improvement of school buildings, the worst features should be dealt with at once and continuous effort made in the direction of improving the physical plants of the schools.

### Malnutrition and the Scales

The use of the scales in nutritional clinics, fully discussed by Frank L. Rose, clinician, Michigan Department of Health, in the May issue of *Public Health*, must be checked up by other observations. The use of the scales as a regular and consistent measurement of nutritional progress is recommended, but emphasis is placed upon the graphic charts of normal growth measurement and the interpretation to be placed upon departures from the "average."

Dr. Rose has adopted the method of assigning relative values for a one hundred point diagnosis: (1) General appearance as to vigor and alertness, 25 points; (2) Musculation, 25 points; (3) Color or complexion, 25 points; (4); the scales, 25 points.

The scales should be utilized in all cases under continuous observation. Extreme departures from the average are convincing that something is wrong in alimentation or nutrition, whether other signs are present or not.

# LOESER'S INTRAVENOUS SOLUTIONS

INTRAVENOUS INJECTION IS A SERIOUS PROCEEDURE THAT REQUIRES

**FIRST:** Selection of Standardized Solutions, from a Reliable Laboratory.

**SECOND:** Full Knowledge of the Contents of the Solution.

Half secret compounds, unscientific gunshot combinations, specialties and low priced substitutes are out of place in intravenous medication.

Loeser's Intravenous Solutions are not "cures" or "specifics," but simple scientific solutions of U. S. P. and standard remedies of established therapeutic value. The contents are plainly stated on the label, free from ambiguity, mysticism and charlatanism. They are standardized by chemical, physical and animal tests.

*Clinical Reports, Reprints, Price Lists and "The Journal of Intravenous Therapy" will be sent to any physician on request*

## NEW YORK INTRAVENOUS LABORATORY

100 West 21st Street

NEW YORK, N. Y.

*Producing Ethical Intravenous Solutions for the Medical Profession Exclusively.*

The Dermatological Research Laboratories were first in the United States to produce Arsphenamine.—Due to the systematic efforts of our research staff, with laboratory facilities and personnel adapted to intensive concentration largely in this particular field, we are now producing a

## NEO ARSPHENAMINE

of such low toxicity and high therapeutic effect that it may be regarded as a super neo arsphenamine.

For the convenience of physicians who have not ready access to reliably distilled sterile water, we supply a bulk package (illustrated) containing 10 ampoules of any one dosage of neo arsphenamine with 10 ampoules of chemically pure sterile water (free from organic matter.) Solution may be effected in the ampoule and syringe.

## Kansas Compares Dietaries

**P**RACTICAL questions having to do with the relative efficiency of the dietaries of nine institutions, educational and correctional, in Kansas have been definitely answered in "A Dietary Study" recently written by E. H. S. Bailey, professor of chemistry, University of Kansas, and chemist to the State Board of Health. A study was made of the food under normal conditions over a long period. The publication is a condensed statement which includes a tabulation of the varieties of the goods furnished. The objects of the investigation were to find out as far as possible: (1) Whether the quantity of food used is sufficient for the inmates. (2) Is the quality satisfactory? (3) Are the different nutritives so distributed that there is a sufficient proportional quantity of carbohydrates, fats, and proteins? (4) Is it possible to substitute cheaper foods for those issued and still keep up the proper dietary? (5) Could any other foods be added to the menu with advantage to the inmates? (6) Is there any unnecessary waste in preparing, dispensing, or serving the food? (7) Are all the waste products utilized as far as possible by feeding to animals and in similar ways? (8) Can the variety of food be increased without additional expense?

In the comparison made between the dietaries, a remarkable agreement was found in the calories used at the two hospitals. The energy value of the food served at Lansing prison was found to be higher than necessary, it being 4,780 calories, though it was noted in passing that the caloric value of foods in the Texas prison farms is 5,429 and that of the Louisiana farms 4,196. The Industrial School for Boys, carried a much higher protein diet than that of the Industrial School for Girls, but the proportion was considered right in view of the extraordinary amount of food utilized by the growing boy.

In the matter of costs, on the basis of 100 for the cost of 1913, the schedule of prices has increased to 203 for 1920. The comparison of cost tables, of methods of accounting, both as to costs and as to balance of ration, should be immensely helpful to administrative officers of institutions. The report recommends the greatest of care as to the menus for each day. To serve only starchy food for one meal and overbalanced protein for the next will not satisfactorily nourish the body.

There seems to be more difficulty in the smaller institutions to check up the actual food used per month or per day than in the larger ones. Careful study of the individuals being cared for is essential in deciding what, all things considered, is sufficient. Generally speaking, it is held that great care in issuing supplies serves to cut the aggregate cost, and that intelligent distribution of materials more adequately meets the nutritive needs, certain foods being more plentifully supplied in winter months. The economy of providing abundant milk supply is pointed out.

### Home Made Diabetic Bread is Palatable

Perhaps the most outstandingly modern departure in the handling of disease consists in the stress that is being given to the education of the patient so that he can cooperate with the doctors in the treatment. That this is particularly important in the handling of diabetics was brought out in the discussion of Dr. E. I. Spriggs in a symposium on diabetes before the Medical Society of London, and reported on *The Lancet*. During the preliminary laboratory examination of the patient under weighed diet the scheme of diet is drawn up. Carrying out the diet in the home depends, as a rule, upon the patient.

Dr. Spriggs has recently introduced at Duff House a short course of instruction for patients and class demonstration is made of how to weigh certain portions of food accurately and how to make special dishes, including diabetic bread. The scheme includes simple instruction by a doctor in the nature of foods and food-stuffs, food values, the reasons for the dietetic measures adapted in diabetes, and the construction of the patient's own diet. The judicious instruction about diet does away with needless apprehension, for the patient comes to understand that his welfare depends largely upon his own cooperation, and that in such control of his own diet the progress of the complaint is postponed indefinitely.

Most of the diabetic breads offered to the public, with the exception of a few well known brands, either contain a great deal of starch and sugar or are unpleasant to the taste, while all are expensive. Patients, therefore, are well advised to do without bread or bread substitutes altogether, eating boiled greens with meat, and lettuce

or tomatoes with eggs. But the need for a bread substitute remains. A particular disadvantage, even with reliable breads, is that they contain a good deal of fat. Dr. Spriggs suggests the following formula for a fat-free casein bread, (Duff House Home-Made Diabetic Bread):

One gallon of separated milk is placed in an enamel dish and warmed, with stirring, to 100 degrees F. A mixture of 1½ fluid oz. of glacial acetic acid and about ¾ pt. of water is prepared and poured into the milk at 100 degrees F., with constant stirring. The caseinogen separates as a white clot. The mixture is left to stand for about five minutes and then poured through muslin placed on a fine sieve for about two minutes, meanwhile working the caseinogen with the hand so that most of the other milk products and acid may be washed away. The muslin containing the precipitate is taken from the sieve, pressed, placed in a bowl of cold water, and kneaded for about five minutes. The water is now changed six times with repeated kneadings each to insure that all traces of milk-sugar are removed from the casein. The washings are to be tested with Fehling's solution. The muslin containing the white material, henceforth called "casein" is squeezed to remove as much liquid as possible, the muslin opened out, placed on a sieve, and left on the kitchen shelf for a few hours to dry. The casein is now rubbed through the sieve on to the muslin and put back on the shelf overnight or until it is perfectly dry to the touch. About 5½ ounces of the casein in this condition should be obtained from one gallon of separated milk.

To prepare the bread, beat up the whites of two eggs to a stiff froth, add nearly two ounces of the above casein, a pinch of salt and a teaspoonful each of cream of tartar and bicarbonate of soda; leveled off, but not pressed down. Mix lightly together, form into cake or cakes and bake in a hot oven for fifteen to twenty minutes. The tin on which the bread is baked should be greased with liquid paraffin. This gives an unpleasant smell to the oven, but the bread has no taste of it.

The casein can be prepared at any time and in any quantity at the convenience of the housewife. It is best kept in a dry place and in open vessels. The bread itself is made in a few minutes by whipping up the casein with the egg white, salt, and baking powder. Sweet cakes can be easily made from it by putting in a little liquid saccharin and some desiccated cocoanut or other flavoring. When freshly baked the well known and objectionable cheesy taste of diabetic bread is less marked in this bread than in those on the market, but it is important that it be made and eaten fresh; this taste develops if the bread is kept long.

The analysis of the bread as served gives: Protein (nitrogen x 6.25) 52.5 per cent; carbohydrate (starch and sugar), nil; fat (ether extract) 0.2 per cent; 20 g. of it give, therefore, approximately 10 g. of protein.

# Dioxogen = (Hydr. Diox.) Oakland

*H<sub>2</sub> O<sub>2</sub> 12V*

STUDY and practical experience have demonstrated that hydrogen peroxide manifests its maximum efficiency, only when it is free from those impurities which interfere with the prompt and unrestrained liberation of the pure oxygen, on which its action depends.

## Dioxogen

therefore, is universally recognized as the best and most effective peroxide of hydrogen, not alone because of its greater volume of available oxygen, which far exceeds U. S. Phar. requirements, but particularly because of its exceptional freedom from residual substances which would restrain in any way the free release—and full effects—of this all-important constituent.

The value of oxygen as a purifying and antiseptic agent is too well established to require extended comment; its influence on disease germs, morbid processes, and its stimulation of granulation and tissue repair are so well understood, that further statement is unnecessary.

In a word, Dioxogen offers a means whereby a large amount of pure, uncontaminated oxygen may be brought directly to the places where it is required and in the active condition necessary to assure its highest potency.

OAKLAND CHEMICAL CO.  
59 Fourth Avenue NEW YORK CITY

## FROM THE FIELD

Two public health conferences, one dealing with the production and sale of safe milk and the other concerned with the use of toxin-antitoxin as an immunizing agent, will be conducted in Chicago, July 29 to August 15. The meetings are being arranged by the state department of public health, the regional committee of the International Milk Dealers' Association, and local health officers. The purpose of the conference on safe milk supplies will be the drafting of a model ordinance suitable for adoption by municipalities throughout the country.

The tenth annual session of the Pacific Coast Oto-Ophthalmological Society will be held in Salt Lake City, September 14 to 16, the week preceding the meeting of the American Academy of Ophthalmology and Oto-Laryngology at Minneapolis, September, 1921.

The Second Mexican Child Welfare Congress is to meet in Mexico City, January 2 to 9, 1923. Like the First Child Welfare Congress held in January, 1921, it will be under the auspices of *El Universal*, the leading daily paper of Mexico, and the editor of that paper will again serve as president. The Congress will be organized in six sections: Eugenics, medical pediatrics, surgical pediatrics, hygiene, education and legislation. Individuals and public and private associations and institutions interested in child welfare are invited to become members of the Congress.

The Indiana Health Exhibit, held May 19 to May 27 in Indianapolis, was attended one day by 50,000 school children. The exposition consisted of art, science, and government exhibits. Dr. Frederick D. Stricker, state health commissioner of Oregon, and Dr. Paul A. Turner, state health commissioner of Washington, gave addresses.

Louis Resnick, formerly director of publicity for the National Safety Council and editor of the *National Safety News*, has been made a member of the staff of the Safety Institute of America and has moved to New York City to assume his new duties.

Plans for free dental dispensaries in Cook county being formulated by the public service committee of the Chicago Dental society will be furthered by coöperation of one hundred leading dentists of Chicago and vicinity, Dr. Dan U. Cameron, committee chairman has announced. Four thousand Chicago dentists are interested in the movement. It is planned to establish the first dispensary in connection with the county hospital.

The National Committee on Exhibits Showing Advances in Sanitary Science has recently been formed in Washington, D. C. for the purpose of collecting and preparing material for a great popular public health exhibit to be held in the Smithsonian Institution. The members of the committee include: Surgeon General H. S. Cumming, U. S. Public Health Service, chairman; Dr. D. B. Armstrong, National Health Council; Miss Mabel T. Boardman, American Red Cross; Surgeon General M. W. Ireland, U. S. Army Medical Corps; Dr. Victor C. Vaughan, National Research Council; Dr. C. D. Walcott, Smithsonian Institution; James A. Tobey, National Health Council, secretary. Space for the proposed exhibit has been placed at the disposal of the Committee by the Smithsonian Institution, which is visited by more than half a million persons annually. Plans are under way to install exhibit material secured from official and voluntary health agencies. The secretary's office is in the national headquarters of the American Red Cross at Washington, D. C.

At its annual meeting in St. Louis, May 22 and 23 the Medical Women's National Association elected the following officers: Dr. Grace N. Kimball, Poughkeepsie, N. Y., president; Dr. Kate Campbell H. Mead, Middletown, Conn., president-elect; Drs. Martha A. Welpton, San Diego, Cal., Mary T. Greene, Castile, N. Y., and May Agnes Hopkins, Dallas, Tex., vice-presidents; Dr. L. Rosa H. Gantt, Spartanburg, S. C., treasurer, and Dr. Marjory J. Potter, San Diego, Cal., secretary. Dr. Elizabeth Burr Thelberg of Vassar College was appointed chairman of a committee to form plans for cooperation with the American Medical Association Council on Health and Public Instruction.

Seventy-five nurses from the Pennsylvania Department of Public Health who have demonstrated heroism in epidemics, floods, mine explosions, and other emergencies are taking an intensive six weeks' graduate course given by the Pennsylvania School of Social Service in conjunction with the University of Pennsylvania, Philadelphia.

Because of the growing demand for teachers for the sight saving classes that are being established throughout America and the difficulty of obtaining teachers specially trained for this work, a course for teachers of conservation of vision classes is being given at Columbia University this summer from July 10 to August 18. Miss Gertrude Thompson, formerly teacher of the sight saving class of Worcester, Mass., and more recently engaged in research work in Cleveland, will have charge of the demonstration classes. Robert B. Irwin of Cleveland, the chief inspiration of the sight saving class movement since its inception in America in 1913, will be director of the course and will give a majority of lectures.

A conference on vocational rehabilitation was held in Washington May 26 and 27 by the U. S. Veteran's Bureau which was attended by educators, at least two from each of the fourteen districts in which the Bureau operates, and by representatives from cooperation agencies.

The largest industrial training school in the Near East was opened recently by the Near East Relief on the estate of Prince Burhan Ed-Din, son of former Sultan Abdul Hamid. The school will house 1,300 Armenian orphan children from Anatolia who were deported by the Turks. The trades to be taught will include tailoring, shoemaking, carpentry and farming for boys. Sewing and domestic science will be taught girls. The estate is one of the finest in Constantinople. It has a frontage of a quarter of a mile on the Bosphorus, including ten acres of rose gardens. The directress of the school is Miss Emma Cushman of New York, who has spent fifteen years in educational work in the interior of Turkey.

The motion picture theater run in connection with the scientific exhibit of the American Medical Association in St. Louis operated continuously. Sixty different periods of thirty or forty-five minutes duration were scheduled.

# 4 MONTHS' RESULTS

A Springfield (Mass.) woman suffered from flat feet and bunions caused by wearing narrow-toed shoes. A local doctor advised her to wear

## GROUND GRIPPER WALKING SHOES

She did, and he kept careful diagrams of her feet from April 19th to July 10th. The above drawings are reproduced from his records. They speak for themselves.

"GROUND GRIPPERS" are the ORIGINAL muscle-developing health shoes for Men, Women and Children. They are universally recommended by physicians and surgeons. Instead of imprisoning arches and toes, they flex naturally with your feet in every part—at every step. Nerve pressure is relieved—stagnant circulation quickened—weak muscles strengthened—painful swellings reduced—deformed bones straightened. Feet are completely restored to normal shape, vigor and comfort. And these results are permanent.

*"GROUND GRIPPERS" are imitated but never duplicated*

Made only by  
**Ground Gripper Shoe Company, Inc.**  
 146 Brookline St., East Lynn, Mass.

Plans have been made for the establishment of prenatal clinics in the state of Georgia for the training of mothers and the training and examination of midwives in an effort to reduce infant and maternal mortality. These clinics will be established in several cities and counties of the state under the auspices of the child welfare council. Dr. Thomas D. Walker, Macon, will have charge of the work in the Macon district.

New York City officials of the departments of health, streets, and street cleaning have banded together to rid the city of rats. Murray Hulbert, President of the Board of Aldermen, Dock Commissioner John H. Delaney, Street Commissioner Alfred Taylor and Health Commissioner Royal S. Copeland have drawn up plans to protect the city's docks against rats and thus prevent the introduction of bubonic plague into the city through infected rodents. The work of these employees will be to free city property of rats. The board of health inspectors will visit all privately-owned establishments to see that they are free from rats.

Howard University, Washington, D. C., will open a School of Public Health and Hygiene in the fall term 1922 for the training of colored men and women in the field. A School of Social Service and a School of Physical Education, both leading to collegiate degrees, will be within the scope of the School of Public Health.

The Sheppard-Towner Maternity Act has been accepted for the State of Nevada by the Governor, bringing the total number of State acceptances to 42. The Federal Board of Maternity and Infant Hygiene has approved the plans of 33 states for applying the initial funds allotted them under the act. At the annual meeting of the Conference of State and Provincial Health Authorities of North America, held in Washington, May 15 and 16, considerable time was devoted to the discussion of state plans and details of operation of the act, in which Miss Abbott and Dr. Rude, of the Children's Bureau, as well as the state health officers, participated.

Construction of the \$2,500,000 medical school of Western Reserve University will begin as soon as labor conditions become settled. The building is the gift of Samuel Mather whose endowments to the university total more than \$4,000,000.

Sanford DeHart now has supervision over the employment, compensation, hospital, and safety work of the R. K. LeBlond Machine Tool Company, Cincinnati, Ohio.

The course in practical nursing instituted by the New York Infirmary for Women and Children at the Olivia Sage School of Practical Nursing has been opened at the infirmary in Stuyvesant Square at East Fifteenth Street, New York City. It is different from the usual nursing course in that it is designed to equip students as practical rather than trained nurses. Its purpose is to meet a demand for practical nurses who will be especially valuable in times of epidemic. Practical nurses will also be available to private patients who cannot afford to pay a trained nurse's fee. The course at the infirmary will be of one year's duration as opposed to the three years' study and practice required for a trained nurse's diploma. Part of the fund left to the infirmary by Mrs. Russell Sage has been used to found the new school.

The April number of *Public Health*, the monthly bulletin by the Michigan Department of Health, is devoted to dental hygiene with articles by such specialists as Russell W. Bunting, Alfred C. Fones and A. C. Thompson.

Bleached flour has been legislated against by the New York City Board of Health which adopted a resolution effective September 1 providing that flour bleached with a chemical shall be conspicuously labeled with the name of the bleaching agent. The board is seriously considering the prohibition of the sale of such flour.

The United States Civil Service Commission states that there is urgent need at hospitals of the United States Public Health Service for dietitians and reconstruction aides in physiotherapy and occupational therapy in connection with the rehabilitation of disabled soldiers, sailors, and marines. The Commission will receive applications until further notice for these positions. Applicants are not required to report for a written examination, but are rated upon the subjects of education, training, and experience. Full information concerning salaries and requirements, and application blanks, may be secured from the United States Civil Service Commission, Washington, D. C., or the board of civil service examiners at the post office or customhouse in any city.

The preliminary report of the X-ray and Radium Protection Committee is published in the *New Zealand Journal of Health and Hospitals*.

An 84 page book on "The Prohibition Question Viewed from the Economic and Moral Standpoint," and containing the views of hundreds of manufacturers, bankers, lawyers, physicians, and educators, has recently been issued by the *Manufacturers' Record*. Many manufacturers report less lost time, fewer accidents, less incompetence and inefficiency under the prohibition regime.

*Domestic Engineering*, Chicago, has recently published a cleverly written illustrated pamphlet on "The Story of the Bath," which traces the history of the bath from the splendor of the Roman Therma down to the modern necessity of porcelain and nickle-plate. The degree of civilization of a country is in proportion to its bathing facilities, so advances the author, Edwin L. Barker. Albert W. Barker drew the pen and ink sketches.

The city of Winston-Salem, North Carolina, for the past three years has conducted a colored baby clinic.

With the realization that industrial conditions are often accountable for the development of tuberculosis as well as the home, Gouverneur Clinic has made a tuberculosis survey of the Gouverneur district, New York City. Cases discovered are referred to tuberculosis clinics near their homes. Dr. N. Gilbert Seymour, director of the Clinic, is in charge of the work.

The New York County Chapter of the American Red Cross has helped solve health inquiries of 11,881 persons during the past year.

The Mothers' Aid Law has been amended by the Massachusetts Legislature in order to make it apply to mothers with children under the age of 16, if such children are required to attend school. Under the old law, aid was granted only to mothers with children under 14 years of age.

Dr. William H. Park, director of the Bureau of Laboratories of the New York City Health Department has been engaged by the Board of Health of Montclair, N. J., to make a survey of methods of handling milk consumed in Montclair and to draw up a new milk ordinance to replace the one now in force.

# Arhovin

No matter what your favorite local treatment in Gonorrhoea and its complications, you can render it more *promptly* and more *permanently* effective by supporting it with internal Arhovin medication.

For over fifteen years, Arhovin has successfully taken the place of santal oil and balsams in the practice of a host of specialists and general practitioners, because it does not irritate the stomach, or kidneys, nor impart a tell-tale odor to the breath.

Furnished in tins of fifty capsules, each 4 minims.

Dosage: One or two capsules, three to six times daily, after meals.

### **Katherine L. Storm, M. D.**

Originator, Patentee, Sole Owner and Maker

1701 Diamond St., Philadelphia, Pa.

According to a statement from Dr. Walter Laidlow, Executive Secretary of the New York City 1920 Census Committee, the density in population in certain districts has decreased. In 1910 an average of 453 persons an acre lived on 2,866 city acres while in 1920 there was an average of 300 persons only. Eighteen per cent of New York's population lives on 1½ per cent of its area, a congestion of population comparable with no other city in the world.

Dr. Frank N. Freeman of the University of Chicago has been granted \$10,000 by the Commonwealth Fund of New York for the purposes of carrying on research into the educational worth of motion pictures.

A bill recently brought before the French Chamber of Deputies, would provide special coaches for mothers or nurses traveling with children under two years of age. This is intended to mitigate the high mortality of Parisian babies who are sent with their nurses to the country and are endangered by the foul air and drafts from the ordinary day coach.

Headaches caused lost time on the part of 1,255 male and 3,778 female workers, or a percentage of absences due to this cause of 19 for the male and 24 for the female, according to results of an investigation in English factories summarized by Drs. Cobb and Parmentor in *The Journal of Industrial Hygiene*. Causes of headache are ascribed to faulty hygiene, faulty diet, lack of sleep and drinking water. Noise, irritating light, and lack of rest periods are other probable causes.

The Joint Committee for Help to War Devastated Countries reports that in 1921 Denmark entertained 5,584 children from Austria for several months, and that since September, 1919, Denmark has cared for 16,456 Austrian children and 5,428 German children. Furthermore, 120 German children needing special care were nursed in a special camp. Gifts of hospital equipment were sent to Austria and Germany, and 40,000 francs was spent supporting a children's home near Rheims. Food and clothing to the value of 70,000 Danish crowns were sent to Germany and Austria and financial assistance for children amounting to 25,000 crowns was sent to Belgium, 33,775 to Poland and 34,500 to France.

The United Fruit Company of Boston has issued its tenth annual medical report showing that the number of patients cared for in the tropics last year was 208,000 of whom 33,000 were non-employees. Methods and treatment of tropical diseases are discussed and a detailed statistical report made concerning their incidence.

The South Carolina mental hygiene survey, authorized by the Governor and conducted by the National Committee for Mental Hygiene under the auspices of the South Carolina Mental Hygiene Committee, has published a report with the following recommendations: The development of an institution for mental defectives with an annual appropriation of \$100,000 for five years; the development of mental clinics to serve the schools, courts, and the general community; special classes for mentally defective children; and an extension of the juvenile court system.

Nurses of the Minnesota Public Health Association are to tour the state in automobiles and give in certain counties which have requested their services demonstrations covering tuberculosis work, care and feeding of babies, care of the teeth and general public-health education work. Their equipment includes a motion picture machine, scales for weighing babies, a lifesize doll for demonstration purposes, a sterilizing outfit, and other things for use in demonstrating infant care. Wherever possible nutrition classes will be organized and an effort will be made to interest local organizations in continuing them after the nurses leave.

The Galton Laboratory for National Eugenics has issued two sets of revised weight charts for male and female babies, the first showing how the weight of one baby compares with that of all other babies of the same age, and the second, showing the probable percentage of babies healthier than the given baby when it shall have completed its first year.

Detailed equipment for a base hospital of one thousand beds capacity is listed in *The Hospital Corps Quarterly* by T. J. Murphy, Chief Pharmacist, United States Navy. Equipment listed includes medicines, hospital stores (diet), surgical instruments and appliances, nursing appliances, kitchen and laboratory equipment, laboratory reagents, and chemicals, x-ray outfit and accessories, etc.

The industrial program of the National League of Women Voters adopted at the convention in Baltimore includes the following items among others: An 8-hour day and 44-hour week for women with one day of rest in seven; establishment of a minimum wage commission to fix pay providing a proper standard of health and comfort; prohibition of night work for women six weeks before and after childbirth.

Amendments to the New York State Child Labor Law, passed by the legislature and signed by Governor Miller, provide that vacation employment certificates may be used for after-school work as well as for work on Saturdays and other school holidays (but not after 6 p. m. nor before morning school hours) and prohibit girls under 18 years of age from doing delivery work.

According to the report of the Bureau of Compulsory Education, Philadelphia, for the year ending June 30, 1921, the number of children who left school for legal employment during that year was 6,279, as compared with 7,926 for the preceding year; the number of general employment certificates issued during the year was 15,220, of which number nearly half were issued to children just leaving school. Owing to the scarcity of positions many discharged minors have been obliged to return to regular school; girls in considerable numbers, however, have accepted domestic work in private families, attending continuation school as usual. The policy of the Bureau has been to investigate carefully all private homes in which girls have accepted employment before granting the exemption permit for domestic service.

Classes in lip-reading for "hard of hearing" children have been opened in more than twenty of the public schools of Toronto.

As a part of the service of the Kansas Bureau of Child Research, which has its administrative offices at the University of Kansas, Lawrence, the department of psychology of the University is offering the service of its clinics to parents, juvenile judges, and children's institutions, as far as time and the facilities available will permit. To these clinics any children may be brought who appear to be mentally different from other children and examinations will be given free of charge.

**CHILDREN'S  
SHOES**  
that are  
*Scientifically  
Designed*

**M**ANY physicians and nurses are accustomed to prescribe Health Maker Shoes for children, because of the scientific care with which they are designed. Each Health Maker Shoe is built to follow the natural foot contour, to give support where needed, to allow ample toe space, to provide for the proper development of the child's foot at every stage.

The inherent quality in Health Maker Shoes insures long service; the sensible lasts provide for natural and healthful foot growth.

**H. F. MALOTT  
SHOE CO.**

*Manufacturers*

1915 Girard St.  
Chicago

*Neosalvarsan*

(Neoarsphenamine-Metz)

is unsurpassed in reliability, trypanocidal efficiency, and ease of administration.

Neosalvarsan is manufactured by the process used in preparing the original Ehrlich product and offers the physician the ideal means for treating the luetic.

*H. & METZ LABORATORIES, Inc.*  
*One-Twenty-Two Hudson Street, New York*

**IN ACIDOSIS**

All the bases of the body are drawn upon (not only sodium) and lost from the body. When only sodium bicarbonate is given the loss of the other bases is not made up.

The use of KALAK WATER makes possible the administration of the several bases in agreeable form—an important matter when patients must take alkalies for longer periods.

Each bottle carries in sparkling form several grammes of the bicarbonates of sodium, potassium, calcium and magnesium.

**Kalak Water Company of N. Y.**

23 City Hall Place

New York City

## Cancer and Its Non-Surgical Treatment

"Cancer and its Non-Surgical Treatment" by L. Duncan Bulkley is an interesting book but rather voluminous considering the amount of relevant information that it contains. Statistics abound to the extent that the applicable knowledge is lost in a maze of figures. The assumption, which the author upholds didactically, that cancer is a constitutional disease, is not widely supported. He stresses the dietetic, hygienic, and medicinal therapy, and outlines such treatment. He gives due regard to x-ray and radium but with the expressed belief in the futility of such measures without the proper dietetic, hygienic, and medical regime.

His results are not convincing and though the results from surgical procedures are far from gratifying, his statement "the disease (cancer) can certainly be made to disappear and remain absent under careful and efficient dietetic and medical treatment alone" will require more convincing proof than is now had before being given credence by medical men.

William Wood & Co., New York, 1921.

## Tracheo-Bronchoscopy

This book is a translation from the German of Sanitastrat Dr. M. Mann by Dr. A. R. Moodie. Beginning with the historical background, the anatomy is fully discussed, the armamentarium considered, and then follow extensive case histories with bibliography and notes which constitute the text a complete encyclopedia of the subject. Most of the technic described has to do with the removal of foreign bodies, but the author emphasizes the importance of bronchoscopic findings in tumors and general disease conditions of the bronchial system.

William Wood & Co., New York, 1921.

## Clinical Methods by Robert Hutchinson

The seventh edition of the next book "Clinical Methods" by Robert Hutchinson has many additions and corrections. It starts out with a method of history taking with an analysis of symptoms and a discussion on the more important laboratory methods employed by the general practitioner. The book is written in simple style and is put up in pocket size editions so that it may easily serve as a reference book for the practitioner in medicine.

Paul B. Hoeber, New York, 1921.

## Urinary Analysis and Diagnosis

In this admirable book on "urinary analysis and diagnosis by microscopical and chemical examination," Louis Heitzman only those tests are given which can be used to advantage and without the necessity of a completely equipped chemical laboratory and by the general laboratory worker and the general practitioner. The matter is particularly definite in the interpretation of findings. The value of microscopic examination is stressed and great detail attaches to the differentiation between the various types of epithelial cells.

The fairly comprehensive chapter on functional tests is contributed by Dr. Walter T. Dannreuther. The book is an adequate guide to microscopic and chemical method, is well illustrated, and can be fully recommended.

William Wood & Co., New York, 1921.

## The Hygiene of the Eye

"The Hygiene of the Eye," a treatise of 331 pages, by William Campbell Posey, M.D., discusses how sight may best be conserved and the relation of the eye to the general economy. He has called to his aid several specialists, Herbert E. Ives, Ph.D., who has contributed the chapter on "Artificial Lighting," Wm. C. Furber who discusses "Daylight Illumination of Rooms and Buildings From An Architectural Standpoint," O. H. Burritt, Principal of the Pennsylvania Institution for the Instruction of the Blind, who devotes considerable space to "The Education and Employment of the Blind" and "Blindness from an Economic and Social Point of View," and Edward M. Van Cleve, late managing director of the National Committee for the Prevention of Blindness, who writes on "The Popular Movement for Conservation of Vision."

For the benefit of physicians engaged in general practice and the public, there is a full discussion of the commoner diseases of the eye, the ocular manifestations of general disease, and how functional ill-health may be caused by eye strain. To lessen the number of accidents to the eyes in industries is the aim of all industrial ophthalmologists. Particular attention is given to the means which have been successfully applied in the prevention of such accidents.

It goes without saying that the book is written in the lucid style which distinguishes all Dr. Posey's literary efforts. The letter press is un-

usually good; most of the 118 illustrations are excellent, though a few bear the earmarks of antiquity and from a pictorial standpoint, might have been improved upon.

J. B. Lippincott Company, Philadelphia, 1918.

## Psychology and Mental Hygiene for Nurses

When a textbook appears which is designed especially for nurses, doctors, lawyers or other professional groups one stops to consider the background of the group which is addressed and the necessity for such isolation. The nurse's training, her literature, and environment are in a way more limited than other groups.

Perhaps no other science has been developed with the rapidity and applied so widely with varying degrees of accuracy as that of psychology. A simple, fair presentation such as is found in Mary B. Eyre's "Psychology and Mental Hygiene for Nurses" shows where the emphasis is being laid, the type of thing that is interesting to the nurse, and her particular problems. The definiteness and discussions could be isolated and criticised as inexact perhaps, but the essentials of recent development in the field have been included.

The author has given a summary of the psychology of nursing as she sees it. "One of the first things to impress itself upon our attention," she states, "is that it lies within our power to form habits of cheerfulness, courtesy, gentleness, courage and truthfulness." Consideration for others, tact, and accuracy in the institution and in the home are emphasized. These principles should be applied not only to the relationship of nurse and patient but to lawyer and client, physician and patient, employer and employee, and others.

The Macmillan Company, New York, 1922.

## Abdominal Pain by Ortner

"Abdominal Pain" by Prof. Dr. Norbert Ortner is a book which yields much valuable information. It presents many points that are often neglected or ignored and not a few that are generally unknown.

The authors give, however, no definite plan of differentiation. Statements which concern certain types of pain, their occurrence, and location, in special reference to a particular organ are modified by such a maze of possibilities that the reader is left with a rather vague idea as to the significance of any pain in any portion of the abdomen.

Rebman Company, New York, 1922.

# Stanolind Petrolatum

*A Highly Refined Product of  
Absolute Purity—Superior In  
Color To Any Other Petrolatum*

“Superla White” is pure, pearly white, all pigmentation being removed by thorough and repeated filtering. Does not contain nor require white wax to maintain its color.

“Ivory white,” not so white as Superla, but compares favorably with grades usually sold as white petrolatum.

“Onyx,” well suited as a base for white ointments, where absolute purity of color is not necessary. Compares favorably with commercial cream petrolatum.

“Topaz” (a clear topaz bronze) has no counterpart—lighter than amber—darker than cream.

“Amber” compares in color with the commercial grades sold as extra amber—somewhat lighter than the ordinary petrolatums put up under this grade name.

*Standard Oil Company of Indiana guarantees  
the purity of Stanolind Petrolatum in all grades*

**Standard Oil Company**  
(Indiana)

*Manufacturers of Medicinal Products from Petroleum*

910 S. Michigan Ave. Chicago, U. S. A.

## Bergey's Principles of Hygiene

The seventh edition of a book published first in 1901 has been revised and in many respects brought up-to-date in "The Principles of Hygiene," by D. H. Bergey. Naturally, however, with the rapid developments of recent years in hygienic practice, public and private, and the change of viewpoint of infant welfare, tuberculosis, and water purification, there is a disparity of emphasis between this standard work, which really needs to be in the library of the public health worker, and some of the more recent publications. In the opinion of the reviewer some of the tabular matter could have been subjected to the same careful revision which was given to the text of this valuable work.

W. B. Saunders Company, Philadelphia, 1921.

## Sewerage and Sewage Treatment

Until recently there has been a lack of modern textbook covering in one volume the whole subject of sewerage and sewage treatment. The author, Harold E. Babbitt, M.S., here presents a book developed from classroom and lecture notes to meet this need.

About two-thirds of the book is devoted to the design and construction of sewerage systems and one-third to sewage treatment. Briefly, this part of the book on design and construction considers: quality of sewage, hydraulics of sewers, design of sewers and sewerage systems, appurtenances, and materials for sewers. There is a chapter on contracts and specifications and another on pumps and pumping stations. About one-fifth of the book is devoted to a chapter on construction. There is also a short chapter on maintenance.

In the chapter on hydraulics of sewers are given several single page diagrams for the quick solution of the

usual formulae. Problems are also worked out in connection with the diagrams to show their application. The design of a sewerage system is well shown by a typical example accompanied by maps and profile.

That part of the book on sewage treatment first considers the composition and properties of sewage. Following this are chapters on the different methods of treatment. At the ends of the chapter on Activated Sludge, and the chapters on acid precipitation, lime and electricity, and disinfection are given good lists of references.

The book ends with brief chapters on sludge, and automatic dosing devices.

The book is well illustrated throughout. Naturally in a single volume covering such a wide field some of the subjects are not fully treated. However, as a textbook, particularly for student use, it is commendable. ROSCOE H. SUTTIE,

John Wiley & Sons, Inc., New York, 1922.

## Diagnostic and Therapeutic Technic

The third edition of Morrow's "Diagnostic and Therapeutic Technic" contains many additions and changes. New methods of treatment, new diagnostic procedures evolved since the appearance of the second edition have been incorporated in the new text.

In his book, Morrow has endeavored "to bring together and arrange in a manner easily accessible for reference a large number of procedures employed in diagnosis and treatment." For instance, he describes the technic of spinal puncture; thoracentesis; methods of nerve injection in trifacial neuralgia, sciatica; gastric lavage; proctoscopy; renal function tests, etc. His description of blood

grouping is especially adapted to students.

This book is to be heartily recommended to the medical profession. It should be especially useful to the intern.

W. B. Saunders Company, Philadelphia, 1921.

## The Condensed Chemical Dictionary

Compiled to make readily available to an inquiring public information concerning the various chemicals and chemical materials ordinarily met with in commerce a "Condensed Chemical Dictionary" has been brought out by The Chemical Catalog Company. The uses of things, the properties of commercial importance, grades, containers, shipping regulations—derivation, methods of purification, the literature has been combed to bring into compact form for secular users all pertinent information. Time-saving elements for technical workers are also served. Important trade and proprietary names are included, which is highly convenient in the identification of materials. The system of spelling used is that of the American Chemical Society. The work is sufficiently cross-indexed to make it a handy volume for daily use.

Chemical Catalog Company, Inc., New York, 1922.

## Dorland's Medical Dictionary

We have long regarded Dorland as a desk necessity. Dorland up-to-date in the eleventh edition is a distinct improvement in that the many terminologies that have arisen in the fields of research in chemistry, endocrinology, and neurology are included. The definitions are concise but complete, and the tabular matter makes the volume almost encyclopedic in scope although convenient in size.

W. B. Saunders Company, Philadelphia, 1921.

# PUBLIC HEALTH NURSING

Successful public health nursing requires a different training and a different type of individual than ordinary hospital or sick room nursing.

For this reason greater care must be exercised in the selection of public health nurses.

Aznoe's service has a clear and comprehensive idea of the requirements for public health nursing and for this reason is able to serve either the public health nurse desiring a position, or the health department or industry wishing such an individual.

Careful selective service has made Aznoe's Registry of inestimable value to both employed and employer in every case where a public health nurse, hospital nurse, institution executive, dietitian or industrial physician is desired.

An attractive booklet, giving full details of Aznoe's service will be gladly forwarded upon request.

### Wilder's Diabetic Primer

The publication at the present time of a book such as Russell M. Wilder's "Diabetic Primer," of treatment of Diabetes Mellitus is, to say the least, a somewhat dangerous venture. Even the principles of treatment are undergoing radical change so that the best authorities express doubt as to the solution of the dietetic problem. The "generally accepted treatment today" is not the same as it was when the book was written; hence it may already be labeled as a bit out of date. The diet menus and recipes and the instructions to patients are valuable. More might have been included in the tables of food values.

W. B. Saunders Company, Philadelphia, 1921.

### The Blood Supply to the Heart

"The Blood Supply to the Heart" by Louis Gross is a monograph that is a finished presentation of the subject. The ingenuity of the author's technic and his thorough and scientific procedures are praiseworthy. His conclusions are convincing. By virtue of his results, from anatomical, physiological, and pathological angles, many interesting and important clinical points are brought out.

The bibliography is complete. The illustrations are beautiful but lose much of their informative value by the absence of a key.

Paul B. Hoeber, New York, 1922.

### Injuries to the Head and Neck

The name of this book "Injuries to the Head and Neck," by H. Lawson Whale, M.D., is rather misleading inasmuch as the entire aspect of the book is that of a laryngologist and orist rather than that of a general surgeon as might be expected from the title.

Lawson Whale discusses the war injuries to the head and neck which involved especially the ear, nose, throat, accessory sinuses and upper air passages. The book as the author himself states in the preface is not a textbook but rather a compilation of certain broad generalizations of advances made during the war.

The reader who expects to find detailed accounts of indications for operation, description of technic and after treatment will be disappointed in the book. The specialist interested in the development of his field will read the book with pleasure.

Paul B. Hoeber, New York, 1919.

### Injuries and Diseases of the Bones and Joints

"Injuries and Diseases of Bones and Joints" by Boetger and Waters is a well written, well illustrated book of aid to the surgeon in the interpretation of roentgenograms. The book is clear, concise, and to the point. The authors have omitted everything which does not bear directly on the subject. Physics, technic, therapy are not dealt with. The authors not only describe and illustrate by plates the pathological conditions but tell the reader what to look for, what to expect to see in the plates of the different anatomical regions.

To the industrial surgeon, particularly, this book will be of value. Not only do fractures interest him particularly, but other bone conditions which are not the result of trauma come to his attention because so often these conditions are attributed by the patient to some slight injury.

The general medical profession has long been aware of the need for just such a book, and it is with a sense of pleasure that the reviewer places this volume on a convenient shelf of his library.

Paul B. Hoeber, New York, 1922.

## Rebuilding the Man

You are frequently consulted by men who have shot their physical and mental bolt. You may recommend a change and rest. A change, to be most beneficial, must be complete.

### Brown's Physical Training Farm

Affords just the change. A 300-acre farm upon the bluffs opposite and overlooking West Point assures a high elevation with a restful scenic view.

Fresh vegetables, fruits and other produce from the farm, and milk from a herd of registered tuberculin-tested Jersey cattle, bountifully supply the table.

A well-equipped Gymnasium, with steam baths, tennis courts, hand ball courts, horseback riding and swimming, are all a part of the regimen.

A Manor House offers accommodations in individual rooms. The training and physical upbuilding is under my personal supervision.

## Recreation—Its Place in Positive Health

Expression, the Main Business of Life, Is  
Best Acquired Through Spontaneous Play

BY BENJAMIN M. SELEKMAN, NEW YORK CITY.

ONE of the earliest activities of animals is to engage in play. Primitive man sang and danced in obedience to the same impulse which propels the play life of modern man. The play instinct has long been recognized as a normal and primary one, and, although statistics on the subject are difficult to secure, experience offers us substantial evidence of how vital and fundamental is its relationship to health.

It is very interesting to note the physical and psychological effects of the normal expression, or of the abnormal repression, of the impulse to play. The former leads to strength of body and a well balanced mind; the latter prevents natural development.

We all know that exercise builds muscle and stimulates the activity of the digestive, respiratory, and other important organs, but it is perhaps not such common knowledge that a normal amount of play aids the body in throwing off poisonous toxins which accumulate as the result of overwork, fatigue, and worry. Because recreation affords immediate relaxation, pleasure, and happiness, physicians have long since recognized its therapeutic value in the treatment of persons suffering from nervousness, overwork, mental breakdown, or general physical and mental debility. Systematic exercises and games are frequently used to overcome physical defects in children and in adults. A striking illustration of this is the ex-

tensive use of this method in hospitals where ex-service men are undergoing treatments for the restoration of totally or partially disabled organs. M. Froissart, France's eminent specialist on children's diseases, reported in July, 1921, to the Academy of Science that he had successfully treated nervous diseases affecting the respiratory and digestive organs by encouraging patients to sing. The deep breathing entailed has the effect of stabilizing the function of the sympathetic nerves.

### Amusements Do Not Recreate

Someone has recently said that "recreation is no longer merely desirable for our pleasure; it is physiologically necessary in order to retain normal equilibrium in the midst of the deadening monotony and excessive strain of the common life of today, both in the city and in the country."

This need constitutes our leisure time problem, a problem which would not exist if we were all wise enough to plan and carry out a well balanced recreation program in the hours that we are free. As a matter of fact, relatively few people have enough training and knowledge to "recreate," as it were, wisely. Because of the serious modification of our habits of life by the basic industrial nature of our civilization, we need assistance in securing opportunities for the normal and healthful expression of the play instinct. We are very apt to mistake

mere amusement for recreation. Dr. Charles Loomis Dana, professor of nervous diseases at Cornell Medical College, points this out in an article in *THE NATION'S HEALTH* for June, 1921, when he says: "It takes a special training to live a life of leisure and amusement wisely. An extra hour or two of rest might mean opportunity to drink, gamble, go to cheap shows, or to engage in any number of other profitless and joyless occupations. That same time spent in really playing baseball, golf, or tennis, or in enjoying music or reading, would surely yield a greater return to body and mind."

Misuse of leisure time, in Dr. Dana's opinion, is responsible for many nervous disorders which come to his attention. For the young, recreation is insurance against nervous trouble. He believes in organized recreation, holding that "intelligent and constructive planning is necessary to safeguard the individual against following the line of the least resistance, and against aimlessness of attitude that leads nowhere except in the direction of disintegration."

"Recreation is the positive phase of the health program." Though our practice of its principle is yet far short, America is so fully convinced of this concept that we find it emphasized in many channels of our public and private life. At the outset of its participation in the World War, the United States Government adopted

Underwood & Underwood.  
Every foot off the ground. Rapid reaction, stable control, wholesome interest result from well directed competitive effort.

one of the largest recreational programs in the history of the world—not out of sentiment, but because it wanted to have the healthiest and most efficient army and navy possible. Carrying out its belief in the importance of recreation to health and morale, the Government created the now historical War and Navy Departments' Commissions on Training Camp Activities. The major work of these commissions consisted in providing normal recreation programs for soldiers, sailors, and marines in the nation's service.

By reason of the fact that a number of national private organizations cognizant of the benefit of recreation, had been developing resources designed to stimulate wholesome leisure time activities among various groups in the United States, the commissions were able to function almost immediately after their formation. The Young Men's Christian Association, the Young Women's Christian Association; the Playground and Recreation Association of America, the Knights of Columbus and the Young Men's Hebrew Association aided the government to the full extent of their capabilities.

A typical statement showing the recognition of the importance of the expression of the play instinct in the underlying philosophies of a number of private philanthropic undertakings in the United States was issued by the American Red Cross. A recent bulletin says: "A well organized community recreation program may be a great factor in the fight for health. The visiting nurse or the medical inspector has not completed his or her task until constructive measures are supplanted for the activities and habits which lead to ill health. Recreation is the positive phase of the health program."

One of the outstanding movements which has committed its resources

upon the conviction that "recreation is a health builder and retainer" has been that launched against venereal disease. The United States Public Health Service, the American Association for Social Hygiene, the Committee of Eleven, and all other agencies which have initiated programs to prevent the spread of venereal disease, have, without exception, strongly urged the adoption of well rounded recreational programs as one of the leading preventive measures.

Normal recreation not only helps to sublimate the sex instinct, but it provides a means of forming normal companionships. "The ages when boys and girls commit their first sex offenses," states a recent bulletin of the United States Public Health Service, "are in the teens and early twenties."

This craving for excitement, color,

adventure, and romance must be satisfied, the bulletin reads further. Prostitutes and their parasites realize this and, by appealing to normal desires, entrap the weak and innocent by tawdry and sordid recreation that often leaves venereal diseases in its wake. It is quite possible for a community to combat the forces of evil, and to give its young people recreation in a wholesome way. And such recreation is essential as a preventive of the spread of social diseases.

This point is further emphasized on a recent issue of the Social Hygiene Legislative Manual, which holds that "clean, wholesome spare-time activities for both young and old are no longer considered luxuries, but necessities."

During the war the Young Men's Christian Association, the Young Women's Christian Association, War Camp Community Service, the Salvation Army, the Knights of Columbus, the Jewish Welfare Board, and the American Library Association, by providing theaters, libraries, athletics, clubhouses, and other recreational facilities, were an immense value in the campaign against houses of prostitution, unregulated dancehalls, resorts supplying liquor, etc.

Commenting at greater length on the experience of the United States Government in its activities to prevent and control venereal diseases among the personnel of its fighting forces in the recent war, the Manual points out

Underwood & Underwood.  
The comfort of a bath is added to the privilege accorded of a play street near Henry Street Settlement, New York City.

that "no better laboratory could have been provided for a fair, comprehensive test" of the "American plan" of combating syphilis and gonorrhoea, than that operated in the American army cantonments—and "under the most trying and adverse circumstances." The success of the plan proved its definite value. And, as is a matter of general knowledge, "clean and wholesome recreation played its part by providing healthy and entertaining sparetime activities for the men."

### A Four-fold Campaign

So valuable was the "four-fold American plan" adopted by the Army, that Surgeon General Ireland is of the opinion that "any attack (on venereal diseases) which omits either law enforcement, or medical, *recreational*, or educational measures, is not likely to be a complete success." Many communities which have put the "American plan" into effect will bear out this statement as it can be applied to civilian groups. The recreational feature of the plan, although having less of a legislative bearing than the other measures, is nevertheless well worth considering. It is less a problem for the state than for the community, and its cost is not the main item. Some of the most effective activities have required little money. They have accomplished fine things through vision, organization, and the stimulation and coordination of existing resources.

Not only is "recreation essential to the prevention of venereal diseases," but it is equally essential for the prevention of juvenile delinquency, which, we should remember, is fundamentally a disease. Specialists in this field have ever advocated adequate playgrounds and recreational facilities as a means of decreasing juvenile delinquency. Experts on child psychology infer that the commission of crimes by juveniles is due either to mental defectiveness or to certain biological defects (such as the abnormal growth of certain glands) or to the perverted expression of normal instincts, chief of which is the play instinct.

Our whole attitude toward the problem of juvenile delinquency has been revolutionized during the last two decades. Children's courts and probation systems have been established in many quarters—to function after the damage has been done. And recreation centers, playgrounds, and parks, have been administered by private groups and by municipalities, who

International.

Setting up exercises on the sands before the morning dip in the Sound at Camp William Carey, Jamesport, L. I., where two thousand boys enjoy a two weeks' vacation each summer as guests of the Boys' Club of New York. Here definite training is combined with play activities.

have been cognizant that such equipment constitutes insurance against delinquency. For example, a study made by Allen T. Burns, revealed that a decrease in juvenile delinquency of practically 30 per cent was coincident with the opening and maintenance of parks in the South Side of Chicago. This result covered a radius of blocks within a mile of the parks. From St. Paul, comes the report that juvenile delinquency in a section from which most of the cases in the juvenile court had come, had decreased 50 per cent following the opening of a social center in the neighborhood. Judge Ben B. Lindsay adds to this the observation that five hundred from among eight hundred girls who came before him recently for delinquency gave "loneliness" as a primary cause of their downfall. And in Dallas, Texas, a reduction of over 80 per cent in the number of Juvenile Court cases from a certain cotton mill district was noted to have followed the establishment of a play park in that locality.

The Director of the Chicago Crime Commission recently summarized in the following words this phase of the relationship between recreation and juvenile normality and health:

In retracing the tortuous path of the youthful criminal, it is seldom found that the trail leads back to the playground, the diamond, the athletic field, or the community center. \* \* \* The young delinquent has, in the majority of instances, grown up in the atmosphere of the saloon, the poolroom, and similar hangouts.

The boy is a gregarious animal. While in his teens, unless restrained, he chooses his playmates wherever he finds them. This desire for compan-

ionship takes on an added importance as he grows older, as it then becomes a matter of selection. If not born to command, he looks to others. The boyhood game of "follow the leader" becomes real, and the influences exerted on the receptive mind of the youth will make or break the man, in the majority of cases.

In the large urban centers, the article goes on to state, due in great part to congestion, the bad influences more than counterbalance the good. The boy is cramped and handicapped when his instinct calls for play and roving, and he easily gravitates toward the corner loafing place or other hangouts of older men. He is getting his first lessons in "follow the leader," and the one who can show him the best time during his leisure hours will have much to do with moulding his character.

Of course, the obvious preventive for this sort of thing is healthy recreation, such as that promoted by Community Service, New York City. "The more social centers, baseball and football fields, playgrounds and open spaces, the less crime. The spirit of sportsmanship which is inculcated at such centers has a lasting influence on the mind of the young." There are approximately twenty-eight million children in this country between the ages of five and eighteen. Of these perhaps seven million live in cities of over one hundred thousand population. Taking into consideration the inadequate provisions made for children, both with respect to physical recreation as well as mental stimulus, it is little wonder that we have sporadic outbreaks of juvenile delinquency.

The animal spirit, which must find an outlet, plus the criminal instinct, which the boy may possess, lead to the tragedy of young offenders.

In spending some \$7,175,000 for playground and recreation centers during 1920, 443 American cities expressed tangibly their faith in the recreating value of play. In 1919, seventeen American cities voted a total of \$13,510,000 in bond issues for recreation purposes, realizing that adequate facilities for the wholesome use of leisure time not only promote health by opening channels of occupation other than those often found fruitful of ill health, but provide means for directly improving the physiques of thousands of citizens, old and young.

In business, too, recreation has been long since recognized as a valuable aid in maintaining the health, morale, and personal efficiency of workers. During the last decade, scientific management has come to the fore. Industrial engineers have been advocating the elimination of waste in industrial establishments through improved organization. It is significant that the establishments which have developed the best methods of management include a recreation program as part of their technique of organization. And these play activities, far from being actuated by pure sentiment, are operated for financial profit as well as for public service. For economical production is one way of increasing profit, and they have found that the healthy and contented employee is the most productive employee. And they know that a recreation program is important in maintaining his personal efficiency.

Among organizations which add a recreation budget to their operating overhead are many well-known concerns such as the Metropolitan Life Insurance Company, the Goodyear Tire and Rubber Company, the H. C. Truck Company, the Endicott-Johnson Company, William Filene Sons Company, B. Altman and Company, and the National Cash Register Company.

An outstanding example is the Joseph and Feis Company of Cleveland, manufacturers of men's clothing. From the point of view of scientific management, this factory, recently built, is considered a model. A considerable amount of capital has been invested in it, including as a part of the equipment a large auditorium, bowling alleys, a swimming pool, handball courts, and an outdoor athletic field—capital otherwise

intended for investment for production. This company not only encourages recreation after working hours, but it has the luncheon hours so organized that a good part of the time is spent in recreational activities. The women many engage in community singing in the auditorium, or they may dance or play athletic games. The men may bowl or play baseball. In addition to the recreational program organized within the factory, the management stimulates dramatics, hikes, picnics, and other group activities. Indeed, it takes so seriously the matter of helping its employees get adequate opportunities for normal recreation, that it employs on its staff a person whose function it is to organize and carry on a well rounded play program in the factory.

Arthur Pound, in an article, "The Iron Man" in the October, 1921, *Atlantic Monthly*, points out that, with the expansion of our industrial life through the development of automatic machinery, the community will need more and more to concern itself with how the worker spends his leisure. "The attendant of automatic tools," he says, "does not live while he is on the job; he exists against the time when he can begin to live, which is when he leaves the shop. His task

does not call for a fraction of his full powers as a sentient being, or monopolize his interest. His hours given to tending automatic machines are given to buy leisure; and in that leisure the operative lives. He lives in his sports, at the movies, at the prize-fights, at the blind pig, as well as at the theater, the lecture, the library, the park, and on the front porch of his inamorata."

The play instinct *will* find expression. Whether the expression be such as will contribute to the general health of humanity depends entirely on where and how people play, and on what they play at. Whether the play life is to be insurance against ill-health, as Dr. Dana urges that it should be, or whether play—or the lack of an adequate amount of play—is to be a contributory cause of ill health, can largely be determined by the community. Mr. Pound concludes that "the welfare of our people . . . depends upon our educating youth to use reasonably and gloriously the growing leisure which the common use of automatic machinery has in store for humanity."

And so far as to educate for leisure means to educate for recreation, the inferences from the present study seem to coincide with those which Mr. Pound has drawn in his article.

## The Cancer Problem

A NOTABLE book by an American surgeon has been recently published in Europe under the caption "Le Probleme du Cancer," being a translation of the "Cancer Problem" by Commander W. Seaman Bainbridge of New York. At the time of its publication (1915) it was well received as it was recognized to give a comprehensive and discriminating account of the cancer situation then. The present edition is of somewhat peculiar interest, it being the first book to be issued from the press of the Three Kings of Louvain University since the buildings of that venerable university were burned. The translation is by Dr. E. Hertoghe of Anvers, the greatest authority on the thyroid gland and the diseases due to its abnormalities. This edition has been revised throughout and brought up to date in all essential details. The author believes in surgery for the relief or cure of malignant tumors but has good words to say for radium and x-rays as adjuvants to operative intervention or in certain cases to be used

alone. However, Dr. Bainbridge insists that in order to obtain satisfactory results the surgery must be skilful and the technic extraordinarily careful; if not, the outcome may be worse than if no operation had been performed. The author has no faith in treatment by medical measures or by diet, although he thinks that careful diet may be of value in preventing malignant disease.

Perhaps the most instructive part of the book is that which discusses the education of the public in relation to cancer. The view that the only way in which cancer can be treated with any success is by early diagnosis and the employment of prompt methods, is universal. But the public must be educated to consult a medical man when symptoms which might be of a cancerous nature exhibit themselves and, moreover, a medical man who has had experience of the disease must be consulted. Unfortunately, only a few medical practitioners have sufficient knowledge of malignant disease to make an accurate diagnosis of it in its early stages.

# Incidence of Heart Disease in the Community\*

Out of Systematic Study and Full Records in Every Case Will Grow Adequate Preventive Methods

BY LOUIS I. DUBLIN, PH.D., STATISTICIAN, METROPOLITAN LIFE INSURANCE COMPANY, NEW YORK CITY.

A DISCUSSION of the incidence of heart disease in the community is especially pertinent at this time in view of the high death rate from this disease that has prevailed during the present year. We in the Metropolitan Life Insurance Company have an advantageous position watching the experience among the many millions of our policyholders. We can see month by month and, in fact, week by week, just what conditions of health prevail in the country at large. Since November, 1921, and continuing each month to date, the death rate from heart disease has been appreciably higher than it was during the corresponding months of the previous year. The same has been true for the associated organic diseases, such as, Bright's disease, cerebral hemorrhage, and apoplexy. It must be remembered that the last three years were favorable ones for heart disease mortality. The rates for 1919, 1920, and 1921 were the lowest recorded during the last decade. When the increase began in the winter months of 1921, the change attracted little attention. The possibility that it ushered in a definite check in the favorable downward tendency for heart disease mortality was not seriously considered. But, by the end of January, 1922, there could be no longer any question that a definite upward tendency was in progress. As will be seen from the graph, the heart disease death rate increased sharply month by month until in March the rate reached the maximum of 168.2 deaths per 100,000 living, one of the highest figures recorded in recent years among Metropolitan Industrial policyholders. (Chart I)

Obviously, some of this increase for heart disease is the direct result of the influenza epidemic which broke out in the early months of this year. But this cannot be the whole cause because heart disease death rates that were higher than normal prevailed for several months before the influenza epidemic and have continued for several months after its close. The experience among insured lives would seem to indicate that we are experi-

*The fundamental importance of collecting all pertinent facts in regard to the incidence of heart disease in the community is urged. Uniformity of record, with such details of history and physical findings as will enable comparison, would bring out a mass of data which would justify definite prognosis which is now impossible. Effective preventive work on a wide scale must await such a mode of procedure.*

*Nor should such data, to be effective, be drawn exclusively from mortality records. Morbidity records need to be so extended as to point out the incipient case, and the predisposing environmental or constitutional condition which led to disabling heart lesions. Our present statistical studies are seriously inadequate in this regard.*

encing in the current year a serious increase in the incidence of heart disease deaths quite apart from the effect of influenza and pneumonia, im-

portant as these two conditions are in affecting the heart disease rate adversely. We shall have to watch the developments for the rest of the year very carefully.

These facts are disturbing to all engaged in public health work because the figures for recent years had given some encouragement that a definite downward tendency had come for heart disease. It must be remembered that the great improvement in the rate for tuberculosis has left heart disease in the first place as the leading cause of death. During the first eight years of the decade, there was hardly any decline in the figures among insured lives. In the general population of the Registration Area, there was an almost continuous increase in the mortality from heart disease. But, in the years 1919, 1920, and 1921, the great improvement in the figures already referred to gave cause for hopefulness that a new situation had been inaugurated. Conditions at the present time are not very encouraging in this respect and would seem to indicate that the favorable heart disease mortality experience of the last few years was possibly only a temporary one, reflecting in part the result of the influenza epidemic of 1918 and 1919, when a large number of advanced cardiac patients were very likely eliminated, and also the effect of improved economic conditions for the wage working population during the war. It is a good deal of a question in view of all the facts, as shown in the following graph, whether there has been any lasting improvement in heart disease mortality during the last decade. This disease is today the chief cause of death. It is likewise a condition of the greatest importance from a public health standpoint. In spite of its leading position in mortality and morbidity, there has been virtually no gain in its control; the campaign against heart disease is very much in the same position as that against tuberculosis fifteen or twenty years ago (Chart II).

The incidence of any disease may be studied from two angles: (1) as a cause of sickness and, (2) as a cause of death. In respect to sick-

Chart I.—The heart disease rate increased sharply month by month until in March the rate reached the maximum of 168.2 deaths per 100,000 living, one of the highest figures recorded in recent years among Metropolitan industrial policy holders.

\*Read before the Boston Association of Cardiac Clinics, Boston, Mass., May 18, 1922.

Chart II.—Conditions at present would seem to indicate that the favorable heart disease mortality experience was possibly only a temporary one. All facts considered, it is a question whether there has been any lasting improvement in heart disease mortality during the last decade.

ness or morbidity, we have very few facts indeed. There is very little authentic information on the prevalence of various types of heart affections. More recently, some information has been accumulated on the prevalence of heart lesions among school children as a result of the work of school medical inspectors. The examinations are, however, often made and recorded in a perfunctory manner. The greatest variations appear in the tabulations. It is not always possible to determine whether the figures include functional as well as organic disturbances. The result is the greatest variability, some cities showing an incidence of two per cent of the children affected and others less than one-half of one per cent. On the other hand, careful examinations have been made among certain industrial groups which show a considerable prevalence of heart affections. The findings of Dr. Schereschewsky of the United States Public Health Service among garment workers in New York; of Robinson and Wilson among employees in various industries in Cincinnati; and of Harris and Dublin among food handlers in New York, indicate that about two per cent of working adults have organic heart disease of one kind or another. The army medical examiners in connection with the draft and camp examinations rejected about four and a half per cent of those examined because of heart defects. The figures will, of course, vary considerably with the group of persons examined, the severity of their occupations and the age of the men ex-

amined. But, altogether, the evidence would seem to indicate that at least two per cent of the population show cardiac defects on examination. This means that in the population of the United States, more than two million persons of all ages suffer from serious heart impairments. This fact alone indicates the magnitude of this particular health problem, and what provision we must expect to make in the next decade to provide for the discovery and the care of these persons.

The statistics of heart disease mortality are more satisfactory, both in point of areas covered, of detail as to color, sex and age, and of diagnostic accuracy. Deaths are reported, even if the cause is not always stated absolutely clearly, especially in conditions where heart disease is associated with disturbances of the vascular and renal systems. Valuable use may be made of the figures, however, both in the reports of the Registration Area, and more especially for persons insured in the larger companies. I am in a position to present the figures for the ten-year period 1911 to 1920 among the many millions of persons insured in the Industrial Department of the Metropolitan and to show the incidence of heart disease as a cause of death at the various age periods of life, in each one of the main classes of this group, that is, among the white males, the white females, the colored males, and colored females.

Before we proceed, it is well to

explain just how we measure the mortality from the several diseases. The index, or death rate, is the number of deaths from any disease during a calendar year for each 100,000 persons exposed during the year. The figures in the following table are obtained in this way. The only point to be remembered is that the rates are specific and refer to the particular class of persons designated. Thus, the rate 7.1 in the column "white males" at the ages one to four years means that seven deaths from heart disease occurred among white male children ages one to four for every 100,000 such white male children who were insured in that year. The other figures are obtained in a similar manner—(Table I and Chart III).

The first point that comes to view from an examination of the tables and of the graphic illustration is that the incidence of heart disease as a cause of death increases consistently with age. At the age period 35 to 44 when persons should be at the height of their productivity, one white person dies from heart disease in every thousand living and two colored persons out of each thousand. At the age period 65 to 74, the number of deaths from heart disease has increased to about 15 in each one thousand living, or to put the facts in another way, deaths from heart disease constitute 9.3 per cent of all deaths at ages 35 to 44, but, at the older period, 65 to 74, they are responsible for 21.9 per cent of the

Chart III.—Statistics of heart disease distributed according to color, age and sex, and diagnosis indicate increased incidence with age, greater incidence among colored persons than white. The rates are higher for females in the age groups below thirty, but higher for males from that age onward, the difference being regularly greater for males with advancing years.

TABLE 1. Death Rates per 100,000 from Organic Diseases of the Heart. Metropolitan Life Insurance Company, Industrial Department, 1911 to 1920.

Age Periods	White		Colored	
	Male	Female	Male	Female
All ages	118.1	132.3	189.1	200.4
1-4	7.1	5.9	13.4	17.5
5-9	14.0	16.7	12.1	16.5
10-14	21.8	29.1	20.2	23.9
15-19	28.9	30.0	28.6	36.7
20-24	27.6	30.8	32.4	40.2
25-34	47.5	45.3	83.2	75.7
35-44	108.6	89.3	199.0	199.8
45-54	245.1	195.2	403.1	414.5
55-64	622.2	516.0	883.0	785.6
65-74	1,607.0	1,445.9	1,717.0	1,570.0
75+	3,153.5	2,910.4	2,674.1	2,662.1

deaths. There is no exception to this rule. The rates are also very much higher for colored persons than for whites. The sex ratios of heart disease mortality are also rather interesting. The rates are usually higher for females than for males up to age 30. From that age onward, the rates for males are higher, the difference becoming regularly greater with advancing years.

But, if heart disease is particularly important in middle life and at the older ages, it is already an important condition in childhood and early adult life. Thus, the number of deaths between the ages of 5 to 9 are as many as from two such important infectious diseases of childhood as measles and whooping cough. Between 15 and 24 years, the deaths from heart disease are more numerous than from typhoid fever. Between the ages 25 and 34, heart disease caused each year almost as many deaths as lobar pneumonia. So heart disease is not to be overlooked as a factor in the mortality of young people. It takes a heavy toll throughout life.

It is difficult to understand just why the rates for young girls after age 5 should be much higher than for boys at the corresponding ages. Perhaps the same causes are at work which make the death rates from tuberculosis higher among growing girls than among boys. The greater prevalence of heart disease among colored people is notorious. Colored males show rates from heart disease during the main period of life from 65 to 80 per cent higher than for white males at the same ages; those for colored women are twice as high as for white women at a number of age periods of life. Possibly, the higher prevalence of such diseases as syphilis, malaria, and typhoid fever in the colored race plays an important part in creating the excess of heart disease mortality.

Some relations have been discovered to exist between the prevalence of heart disease and occupation. While the figures are not entirely trustworthy, it would appear that of all occupations, those which are carried on upon the water have the highest heart disease rates. Thus, sailors, fishermen, and to a less degree, barge-men, show a very high prevalence of heart affection. It is possible that this relationship is in some way related to exposure to greater dampness and cold. Next to these occupations are those exposed to alcoholism, including brewers, and those exposed to lead poisoning. There are high rates for metal workers, blacksmiths, and especially for cutlers and tool makers. All sedentary occupations have favorable death rates from heart disease.

### Summary

To summarize the facts then, we may say that, according to our best knowledge, there are about two and one-half million persons in the United States who, on examination, would show some type of organic heart lesion. These persons are not all sick. Many of them are engaged in their ordinary pursuits and have no idea of their impairment. Yet, they are seriously impaired lives who, unless they take note of their condition and adapt themselves to their lesser capacity to labor, will break down at a premature age. Insurance studies have shown that persons impaired with such minor defects as mitral regurgitation have, as a group, double mortality for their age. It is the business of American physicians, and especially of those in the cardiac clinics, to discover for each community those who are in any way suffering from one type or another of heart defect. No one knows the amount of loss sustained annually through the disability for work which results from the varying incapacity among these two and one-half million people.

In addition, there are each year in the United States about one hundred and fifty thousand deaths from heart disease and the number is not declining. Even under age 45, there are each year over 22,000 deaths. Each one of these deaths represents a distinct loss to the community since these persons are, presumably at an age where production may be expected to be at its highest. They leave good sized families of minor children who suffer from the loss of a parent and, more usually, the father. This is the extent of the community problem which is brought about each year by heart disease.

It is very obvious, however, that our information with reference to heart disease both as a cause of sickness and of death is very fragmentary. At the present time, there is really no agency or machinery for collecting the facts by means of which the campaign against heart disease can be properly guided. It is just this sort of machinery that is called for at the present stage of the movement. This information will provide checks against misdirected enterprise, and will suggest which of many possible lines of activity are really worthwhile.

What promises to fill this need is the plan of the Association for the Prevention and Relief of Heart Disease in the City of New York. This Association, which conducts a considerable number of cardiac clinics, proposes to keep systematic records in connection with its work. The greatest emphasis has been placed upon a full history in each case, and on a complete record of the findings on each examination. A series of follow-up visits by social workers is planned, and the findings from this source are likewise provided for in the record. A system of tabulation and of analysis is being considered, so as to answer the outstanding questions which the directors of this Association have in mind. It is hoped that out of these records it will be possible to throw light on the prognosis in various types of cases, on the duration of the various heart lesions from inception to death and on the value of certain types of treatment in relation to the restoration of working capacity. A goodly number of other factual items will naturally suggest themselves at the outset of a campaign against a disease of such magnitude as heart disease. We append to this article a reproduction of the first page of the record form (Fig. 1).

What is being planned for the city of New York should, of course, be seriously considered by associations of heart disease clinics in other cities of the country. It is certainly to be hoped that the clinics of such cities as Boston, Chicago, and Philadelphia, whether carried out under municipal or private auspices, will develop a similar system of records and plan similar tabulations and analyses. The greatest value of this effort will come from the multiplication of sources of information and out of the exchange of experience from place to place.

What will probably remain a most fertile field for the development of knowledge is the practice of individual physicians who must, for a long time, continue to be the chief instruments in the campaign against heart disease. The individual doctor should appreciate, more and more, the necessity of keeping a full history and current record of his cardiac patients. The record form recommended for use in New York City should be indorsed by the leaders of the profession, and its use encouraged by the great body of physicians. It will then be possible at regular intervals to send the material to some central agency where the records might be tabulated and the conclusions made available to the whole profession. On a foundation of established fact, the campaign against heart disease will make rapid and substantial progress.

Fig. 1.—The greatest emphasis is placed upon systematic records in each case of heart disease. This record form, adopted by the New York Association for the Prevention and Relief of Heart Disease provides for full history and complete record of physical findings on each examination. Such records will develop possibilities of prognosis in given conditions.

## Land—Recreation—Health

BY KENNETH F. DUNCAN, FIELD SECRETARY, THE HARMON FOUNDATION, NEW YORK CITY.

**D**ID you ever pause to estimate the health value of Central Park to New York City? Do you, in the busy rush of the day, ever stop to consider what your own town may be losing today in the health of its citizens of the tomorrow of ten, twenty or fifty years through lack of open play and breathing spots? Have you ever actually determined to your own satisfaction that boys and girls of your town, right now, today, have a field of their own where normal development may take place and where normal recreation and sport do not constitute trespass? Recently the writer made a survey of a dozen cities ranging in population from fifteen thousand down and was appalled at the surprisingly small number of plots of land centrally located and available for acquisition as play-

grounds. Perhaps a walk or drive through the central section of your town or a chat with an up-and-going real estate man will convince you that the acquisition of public land for your town is a matter that can ill afford to be long postponed.

Perhaps you will find playgrounds and athletic fields established. If so, are they on land consecrated to that purpose forever or are they merely "squatters" on land being held for future school buildings or even on privately owned land held for sale? Many a splendid recreation system has been wrecked by suddenly losing its anchorage. Has the public health worker or physician any responsibility in the matter? Undoubtedly the answer to this question is "yes." Should he take any step toward inaugurating the movement to provide land? If

investigation proves the need to exist in his town, the answer can hardly be other than "Yes" to this question, also. The sad effects of lack of play—of outdoor play—on the health, particularly the health of children, are too well known to need reiteration in an article for the readers of this magazine. But outdoor play cannot be insured unless play space—naked land—is provided.

There is an organization whose function is to help small communities acquire public lands for play purposes. This organization is the Harmon Foundation with headquarters at 140 Nassau St., New York City. It is a non-profit organization, founded by Mr. William E. Harmon. The experience of thirty years in the development of real estate convinced Mr. Harmon that attention was not given

sufficiently early in small communities to the vital need of adequate open play spaces, of providing permanent breathing spots as the community grows; that many of the opportunities to acquire good sites at reasonable cost that existed yesterday are gone today; that by tomorrow most of those still available today will be gone. This conviction, coupled with the remarkable effect of the gift of a recreation park and community center on the life of his own home town, resulted in the organization of the Foundation, with a twofold purpose: (1) to bring to communities a sense of the vital necessity of setting aside for all time open play spaces, of providing generations to come with land, the "Gift Eternal;" (2) to render certain definite aid to communities realizing this need.

This help may take one of several forms. First, at the invitation of the municipal authorities, of a Chamber of Commerce, Rotary Club, Playground Association, Women's Club or other representative group the Foundation will cooperate in a city-wide subscription campaign to raise funds to purchase the land required. The services of a Field Secretary will be given for a period of several weeks, without charge of any kind, to organize the children of the town into a unique selling force to "Sell their own playground." This method has been successfully demonstrated; its attendant publicity campaign possesses enormous educational value and stimulates the interest of the community in all phases of recreation. Assistance will also be given in the shape of publicity and organization of a city election campaign if that is decided upon rather than a subscription campaign.

In communities not over ten thousand in population and in a position to conduct the campaign without the services of a field secretary of the Foundation, an outright contribution up to 10 per cent of the amount raised and paid in to the purchase fund may be made under certain circumstances, such contribution not, however, to exceed five hundred dollars. A contribution will not be made to a campaign the plans for which were actually under way previous to June 1, 1922.

In towns under five thousand where a campaign seems inadvisable at this time and where the need appears urgent and suitable land is available at a reasonable price, the Foundation in some cases is prepared to purchase a site at a cost not to exceed two thou-

sand dollars, and to lease it for playground purposes to an association, school board, or other organization for a term of five or ten years, with an option to buy the property at any time within that period at its exact cost plus a low rate of interest to cover interest and taxes. Or, if desired, and the state and local laws permit, the Foundation might deed the property to the town, subject to a mortgage running for ten years and bearing interest at 4 per cent, thus saving taxes. In either case the Foundation would be satisfied to receive back its investment in almost any way, so as to put as small a burden on the town as possible. Payments of one hundred dollars or multiples thereof would be acceptable.

The Playground Division of the Harmon Foundation has but one interest—to awaken communities to a realization of the recreational needs of the children and the health and character building benefits thereof, and then to help those communities to meet that need. It believes that land for play purposes is a primary and fundamental need, and that the proper time to consecrate that land to the child forever is while good sites are still available at costs within reach. The three plans outlined were devised to meet average conditions. If a town has a problem that does not seem to fit any stereotyped method, some other basis of cooperation is worked out. The Foundation is interested only in getting the job done.

## Mortality Past Middle Age

BY I. S. FALK, DEPARTMENT OF PUBLIC HEALTH, YALE SCHOOL OF MEDICINE, NEW HAVEN, CONN.

ONE of the notable contributions of vital statisticians in the few years immediately succeeding the decade 1900-1910 was the proof that in the United States the specific death rates for ages under forty-five were decreasing, and for ages over forty-five were either stationary or increasing, in spite of a decreasing crude death rate for all ages. In the intercensus period 1910-1920 studies of the mortalities of special groups in the population appeared to indicate a state of affairs similar to that of the first decade of the century. The feeling among statisticians has been one of watchful waiting for the appearance of the 1920 census data on the age distribution of the population. Without these figures even reasonably accurate measurement of the trend of mortality in the whole country was impossible. At this time (May,

1922) the Census figures for 1920 have not yet come to hand and it may therefore appear premature to assert confidently what the life tables for 1920 will show. Enough has already been published, however, from the Census Bureau and from reliable statistical offices dealing with smaller population groups to indicate beyond doubt that in 1920 the death rate was lower in every age group than in 1910. It is hoped that the data presented in this note will correct the untimely impression produced by the appearance in THE NATION'S HEALTH for April of this year of a paper on the Increased Mortality Past Middle Age."

In this paper, Dr. MacCarty presented a table of figures on mortality

I. MacCarty, M. T., M.D.: Increased Mortality Past Middle Age, THE NATION'S HEALTH, April 15, 1922, iv, No. 4, 202-204.

TABLE I.—Comparison of Mortality of Males and Females by Age Groups. Death Rates per 1,000 Population. (Registration States as Constituted in 1900)

Age	Males			Females		
	1900	1911	Per cent increase or decrease	1900	1911	Per cent increase or decrease
Under 5	51.2	39.8	-26.57	45.8	33.3	-27.29
5-9	4.7	3.4	-27.66	4.6	3.1	-32.61
10-14	2.9	2.4	-17.24	3.1	2.1	-32.26
15-19	4.9	3.7	-24.49	4.8	3.3	-31.25
20-24	7.0	5.3	-24.29	6.7	4.7	-29.85
25-34	8.3	6.7	-19.28	8.2	6.0	-26.83
35-44	10.8	10.4	-3.70	9.8	8.3	-15.31
45-51	15.8	16.1	+ 1.90	14.2	12.9	- 9.15
55-64	28.9	30.9	+ 6.92	25.8	26.0	+ 0.78
65-74	59.6	61.6	+ 3.36	53.8	55.1	+ 2.42
75 and over	146.1	147.4	+ 0.89	139.5	139.2	- 0.22
All ages	17.6	15.8	-10.23	16.5	14.0	-15.15

TABLE II. Death Rates in the Registration Area: 1910 and 1920.

Age	Death rates per 100,000 population		Per cent decrease
	1910	1920	
All ages .....	15.0	13.1	12.7
Under 1 year..	130.8	96.6	26.1
1-14 years .....	63.6	48.0	24.5
15-44 years .....	69.1	65.9	4.6
45-74 years .....	25.8	22.8	11.6
1-74 years .....	10.5	9.4	10.5
75 and over....	143.6	134.9	6.1

TABLE III.—Mortality from Principal Causes of Death, U. S. Registration Area, 1910 and 1920.

Cause of Death	Death rate per 100,000 population		Per cent decrease
	1910	1920	
All causes .....	1,496.2	1,306.0	12.7
Organic diseases of the heart.....	141.5	141.9	-0.3
Pneumonia (all forms).....	147.7	137.3	7.0
Tuberculosis (all forms).....	160.3	114.2	28.8
Acute nephritis and Bright's disease.....	99.1	89.4	9.8
Cancer (all forms).....	76.2	83.4	-9.4
Accidents .....	84.4	71.4	15.4
Influenza .....	14.4	71.0	-393.1
Puerperal causes (total).....	15.7	19.2	-22.3
Puerperal septicemia .....	7.2	6.6	8.3
Typhoid fever .....	23.5	7.8	66.8
All other causes.....	726.0	563.9	22.3

by age groups, comparing the death rates of 1900 and 1911 for males in the Registration States as constituted in 1900 (the so-called original registration states). It is unfortunate that Dr. MacCarty presented only the figures for males. Had he taken them for both sexes combined or separate he would undoubtedly have been more reserved in his conclusions. In the original tables<sup>2</sup> or in Dr. Louis I. Dublin's more conservative analysis<sup>3</sup> of the data an increasing mortality was evidenced among males for all ages over 45 and among females only in the age groups 55-64 and 65-74, and not in the age groups 45-54 and 75 and over.

In February of this year the Department of Commerce, through the Bureau of the Census, issued a statement showing deaths and death rates by age groups from different causes of death in 1910 and 1920. Since then the contents of this official statement have been made more easily available through republication in the *Public Health Reports*<sup>4</sup> under the title "Death Rate in Every Age Group Lower in 1920 than in 1910." Table I is taken from the paper by Dr. Dublin, and Table II has been prepared from the figures in the Census Bureau report.

It is to be noted that the apparently increasing old-age mortality between 1900 and 1911 indicated in Table I applies to the original registration states and the declining old-age mortality between 1910 and 1920 in Table II to the entire Registration Area. The population data for the individual states have not yet been published and it is therefore impossible to calculate the specific death rates for the populations in any special portion of the Registration Area. There is every reason to believe that the reduction in mortality at the higher as well as at the lower ages of life has oc-

curred in the original registration states in the same manner as in the entire Registration Area, as indicated in Table II.

Table III prepared from the Census Bureau report shows that the death rates for 1920 are lower than those for 1910 not only for all causes of death but also for each of the principal causes of death—tuberculosis (all forms), pneumonia (all forms), acute nephritis and Bright's disease, accidents, typhoid fever and "all other causes"—excepting influenza, cancer (all forms), and puerperal causes (total). Puerperal septicemia showed a decrease. Organic diseases of the heart showed practically no change (an increase from 141.5 in 1910 to 141.9 in 1920).

This note is not written with any desire to throw the proverbial monkey wrench into the wheels of public health progress. It is presented in the belief that the starting point in a campaign against the "degenerative disease" is an accurate statement of the *status quo*. A full statement of the facts about mortality at the higher age groups is not yet possible. The available statistics indicate that the apparent increase in the mortality from these "degenerative diseases," to whatever cause it may have been due in the past, has in the last decade given place to a decline.<sup>5</sup>

5. The Statistical Bulletin of the Metropolitan Life Insurance Company for May, 1922, tables of the specific death rates for the Registration Area as of 1900 are in accord with these conclusions.

## Chicago Provides New Municipal Baths

Chicago's new North Avenue Baths located in the fifteenth ward were formally opened recently by Health Commissioner Herman N. Bundeson. Free swimming instruction is given to school children every Thursday.

# The Educational Factor in Public Health\*

## The Impulse to Get What Is Healthful Is Not Instinctive, But Is the Result of Education

BY FLORENCE MEREDITH, M.D., PROFESSOR OF PREVENTIVE MEDICINE, WOMAN'S MEDICAL COLLEGE, PHILADELPHIA, PA.

PUBLIC health work divides itself rather definitely into three distinct phases which often are not differentiated, (1) research, (2) administration, (3) education. Up to a comparatively recent time the last was not given due consideration. Medical schools were chiefly engaged in producing doctors who could treat disease, and schools of public health in producing research workers and administrators of public health. These doctors of medicine and of public health also developed into public health educators or not, as the case might be. They did so sufficiently often that the value of such work became apparent, and the tendency now seems to be to give particular training in the methods of public health education, both in medical schools and schools of public health.

This does not usually mean cutting down any of the other fields. We need cure as much as ever. One of the ways of preventing many diseases is to cure those who have them, so that they will not be a menace in the community. We need research as much as ever. In fact, we are calling upon sociology and economics to supply the results of their research to be used in public health work, and upon many other non-medical sciences. In the medical field it is the case with many diseases that we need more knowledge before we can do much in the way of educating the public about them.

And we need more training for administration than ever before. Doctors without such training, and even laymen, have done valuable work, but it is appearing increasingly important that those who undertake administration be particularly trained for it in schools of public health. Most doctors would not think of trying to occupy such a position with such training. But we also need special training for the important matter of public health education. It is today less well prepared for than any of the other fields.

The saying of the New York Department of Health that "public health is purchasable" is true only with qualifications. Public health is not purchasable unless the public knows what to purchase, is financially able to purchase it, and WANTS to purchase it.

### The Receptive Attitude

It is here that education of the public is made necessary. We can have no application of the results of research and no field for administration unless the public is willing to accept research and to permit administration. In other words, unless the public has been educated to the carrying on of public health work, research and facilities for administration of work so devised will be relatively futile. On the other hand, no education is wise unless it is based on scientific research, nor can it be made effective without the means of administering what the public has learned to want.

Public health education is at once, therefore, both the most idealistic

aspect of public health work, in that its aim is to establish high ideals of health and is most practical in that it is the fundamental step toward the application of knowledge gained through research.

Science has already advanced enough so that we should have much better health than we now have. Practice is far behind knowledge, partly because of administrative defects, but largely because of the fact that the wisdom of science is not yet popular wisdom. In most places, indeed, we have the machinery for adequate administration if it could be used to its full capacity. What we have not is the willingness of the public and of individuals to utilize both scientific knowledge and the facilities for its application.

There have been in the past several points of view in regard to the preservation of health. The oldest of all was that of leaving the individual to himself, for the most part, to look after his own health, until he became ill, at which time he became a matter of much interest to

The dispensary is a means of relief, but it is no less an educational center where new standards of health care are propagated and new objectives formed which are the best present evidence of increasing interest on the part of the individual in health facts.

\*Read before the annual conference of the Association of Women in Public Health, New York City, November 15, 1921. A succeeding article will deal with methods in health education.

the ancient medicine man and his successors. Even from the beginning, however, there was a tendency to try to control health by controlling the environment. Originally this consisted of the wearing of a charm or talisman. Afterward it became somewhat more logical. Since the days of Murchison and his pathogenic theory we have been trying to benefit the individual's health by making things right around him. For a time health was hardly considered a personal matter at all, but a matter of environment. Our first great decreases in the death rate resulted from improved external conditions. At that stage of our development probably no other methods could have produced so great decreases.

We are now controlling external conditions more intelligently than when we believed in "nuisances" and "miasms" as the chief cause of disease. But we are still trying hard to get at health from the outside. Such efforts are receiving a tremendous amount of well-deserved attention, and results can be shown. Yet in this big work we often lose sight of the fact that the individual is a very great determiner of his own health.

If we bear this fact in mind, we arrive at the present method of health conservation, which is a reaction to both former methods, and a combination of the two. It includes all possible efforts to improve health from the outside, but relies upon the individual to do a great deal for himself. It differs from our original method of leaving on the individual the responsibility for his own health, however, in that now the aim is to

have this individual able to look after the personal aspects of health intelligently.

### External Aids to Health

Those who have been working toward health from the outside—such as those who have built model houses and tenements and furnished every device of health and safety in shops and factories have sometimes been surprised that it has not borne more fruit in the better health of those receiving these benefits. It should not be a surprise, however, for of what use is a rocking horse to a child who can only lie in his cradle and kick? It is not necessarily the fault of the one who supplies bath tubs that they are used as coal bins, or of the one who supplies respirators if they are allowed to gather dust hanging on a nail, or of the one who provides ventilating systems if they are never put into use. But it's somebody's fault that the individual misses the benefit to health through not knowing enough to use them. It may be said that the question of healthful surroundings as a whole is not covered by the illustrations given. This is perfectly true, for a man often benefits from healthful surroundings in spite of himself. Nevertheless the benefit of such surroundings and the educational value they have in themselves is not what it might be in many instances, if all individuals were educated to know what healthful practices mean and what they are for.

Of course an individual may still, without his knowing it, or cooperating to get it, derive benefit from better conditions. An illustration of this

is the practical elimination of typhoid in large cities. The average individual took a small part in making this possible. Typhoid bearing excreta are still distributed as carelessly as ever. Yet the individual has benefited as much as if he had stood by at every step toward pure water.

Good conditions around a man may do much to educate him, too. An illustration of both of these points is the providing of well cooked, suitable food in industrial plants. The worker's health is benefited directly, and indirectly he perhaps develops a higher standard in food, by comparing the food provided with his home dietary. We are every day observing such improvements in standards.

If the worker spends his money for silk shirts for himself, a fur coat for his wife and high heeled shoes for his daughter, it is because these things are considered of more value and the source of more comfort than the joys of health. This wrong conception is certainly partly due to lack of health education. When it is due to sheer stupidity in not grasping the idea of the desirability of health, then only time plus all our efforts will overcome it. But there are far better ways of building up a well populace than waiting for Nature to produce individuals who are so clever they do not need to be told the why and the how of healthful living.

### The Apostle of Health

In order to make whatever is done from the outside worth while, standards must be built up from the inside. It is analogous to the placing of public libraries in a town where most of the inhabitants cannot read. The very fact that the library is there is an incentive to the people to read. But there must be someone with a zeal for reading and for teaching reading—someone who believes that people would be better off for learning to read. Let libraries continue to be built, and at the same time let people continue to be taught to read—a statement that is very trite in this field, accepted by everybody.

We do not always see analogous situations in the field of public health. A careless sneeze may do more harm in a theater ventilated by vacuum and plenum, than ordinary poor air uncontaminated by coughing and sneezing. Chemically satisfactory and physically healthful air is not uncommonly provided these days, but one can hardly be many minutes in a public gathering without witnessing unguarded coughing or sneezing? We

International.

The health protection of the community often hinges upon exhaustive laboratory study of the individual patient. Here, too, the public is coming to understand that precise methods require preliminary study, and in every case involve the intelligent cooperation of the patient.

Underwood & Underwood. Atmospheric tests are here being made in a movie theater. Washed, purified or vitalized air, however, do not protect the community against the "broad-cast" sneeze, or the victim of respiratory disease who does not do his part toward safeguarding his neighbor.

need both good air, and individuals who know enough not to cough and sneeze into it.

The purely environmental method of building health is one-sided, and not very constructive. It is likely to give us individuals in the next generation still trying to balk or reluctantly following the lead of the farsighted, rather than themselves initiating public health measures, as the educated would do.

But the purely educational method would be just as bad. Educating individuals and then leaving them to get what they have been educated to want, is sound from the point of view of developing the racial stock, for it would mean the survival of only the physically fit, and the fighting fit. It has been questioned by some scientists whether we are wise in aiding the unfit to pull through, and to propagate their own feeble kind. But no one has yet convinced us that the conscience of the modern man would permit him to follow anything like the methods of Sparta. Giving him education as to how to survive would place him in a somewhat better position than the infant of Sparta, but even with this many would go down in the struggle. Not only would this method be inhumanly cruel, but it would be unnecessarily slow, considering that the world needs healthy men and women now. The growing belief in the possibility of extensive blastopthoric damage, leads us also to the immediate improvement of health in all possible ways.

The modern method implies provision by the wiser for the needs of

the ignorant, while trying to do away with their ignorance. What a relief it would be not to have to fight to put over some health measure for which people should be clamoring! Even college students often have to be coerced into having physical examinations, or attending gymnasium, or going to bed at a reasonable hour. Only 10% of the individuals offered a complete physical examination by a certain insurance company accepted the offer. Good food in school and factory restaurants must usually be sold at or below cost, or highly unsatisfactory cold lunches will be brought from home. In factories men engaged in lead work must often be paid for the time they are engaged in washing the lead from their hands, or using the shower baths provided.

### His Brother's Keeper

A baby who is supposed to grasp for objects when it is a few months old, will not exhibit this faculty, however, if there is no object near to grasp. The object must usually be dangled tantalizingly in front of him, and then comes the impulse to grasp it. It would be prolonging the progress of his development unduly, and cruelly if the object were his bottle, if the baby were not encouraged by the proximity of the desirable objects.

Often health facilities must be dangled before the eyes of the public before the impulse arises to grasp them. But unlike the case of the baby, the impulse to get what is healthful is not instinctive. People must be trained, for example, to want pure food. But at the same time pure food must be available in the city mar-

kets where they can get it, once the impulse has been aroused. This means that the enlightened must work, often against opposition, to provide for needs that are not yet felt, and at the same time must endeavor to cause the need to be felt. This is what the modern "hygienist" is trying to do. I prefer the term "hygienist" to "sanitarian" because the former seems to connote a wider interest in health, concerned with both the individual and his environment; whereas the latter seems somewhat more limited to the matter of cleanly and healthful surroundings.

In conclusion, research determines in what respects the public should be educated in health matters, and guides administrative practice. Administrators of public health take the standards of research and the ideals of the most enlightened and put them into practice—if possible. But often the advice and consent of the least enlightened is lacking, which frustrates efforts. Education is therefore a fundamental in the field of public health, as will be readily granted by a group of women such as this. But not so readily shall we agree on who shall give this education, where they shall be trained to give it, by what methods they shall give it, how and when and to whom it shall be given.

I think we shall agree, however, that not only should doctors of medicine and doctors of public health and certified sanitarians consider health education a part of their role, but that there must be many other kinds of health educators, to translate the findings of science into the popular tongue.

International.

Good food, bad food, murderous food, are offered alike to an indiscriminating public, but educational exhibits and informational materials are giving out workable standards in food products based upon intrinsic values as evolved in the experimental laboratory. The end is not yet.

# A Compilation of Current Notions on Feet

## Tabulated from Inquiry Made of One Hundred Orthopedists and Thirty-Five Non-Medical Men

By HERMAN W. MARSHALL, M.D., BOSTON, MASS.

**A** QUESTIONNAIRE on the basis of fifty items fundamental to the intelligent management of feet was prepared by the writer and distributed to orthopedists and retail shoe merchants. One hundred orthopedists from many cities of the United States and Canada have replied, and thirty-five non-medical answers have been received.

Part I of this article analyzing the consensus of opinion of orthopedists and shoe merchants on fifty fundamentals of foot requirements appeared in the July issue of THE NATION'S HEALTH.

(30) *Whitman or "Rocker" plates not only hold the feet, but tend to restore sagging arches to former posture. These supports are rather difficult to make and to fit well, also they may be uncomfortable to wear if quick corrections are attempted, yet they are unusually effective in a difficult set of cases.*

Orthopedists agreed, 72=72%; disagreed, 15=15%; doubtful, 9=9%; no opinion, 4=4%.

Shoe dealers agreed, 19=54%; disagreed, 4=12%; doubtful, 1=3%; no opinion, 11=31%.

*Worcester, Mass.*—They have an extremely limited field.

*Detroit, Mich.*—They do not tend to restore sagging arches without developmental treatment.

*Boston, Mass.*—Only for young people and children.

*Chicago, Ill.*—Agreed in very rare cases.

*San Francisco*—Absolutely torturing and unardonable.

*New York City.*—Agreed, but many patients prefer to carry their Whitman plates in their pockets instead of putting them into the shoes.

*Hartford, Conn.*—Once an arch support always an arch support, unless muscles can be built up.

*Atlanta, Ga.*—Dr. F. G. Hodgson: Doubtful.

*Syracuse, N. Y.*—Syracuse Clinic: Doubtful.

*Buffalo, N. Y.*—Disagreed.

(31)—*Anterior arches of the feet are depressed abnormally very often by continuous wear of high heeled pointed toe shoes. When anterior arches weaken, such shoes should be discarded until feet have recovered thoroughly. Restoration of anterior arches is accelerated by temporary use of anterior arch pads and appropriate foot exercises.*

Orthopedists agreed, 99=99%; disagreed, 1=1%; doubtful, 0=0%; no opinion, 0=0%.

Shoe dealers agreed, 30=85%; disagreed, 4=11%; doubtful, 1=3%; no objection, 0=0%.

*Lynn, Mass.*—E. H. Dunbar: Add at end of statement—"and shoes that are of sufficient length to relieve back pressure."

*Chicago, Ill.*—It may not be safe to discard high heeled shoes suddenly if heel cords are shortened.

*Rochester, N. Y.*—Anterior arches are depressed very often by high heeled pointed shoes that have flexible shanks.

*Boston, Mass.*—When anterior arches weaken such shoes should be discarded for all time.

*Boston, Mass.*—Mr. Thomas Burns: The value of physical therapy, massage, and gentle repeated manipulations should be emphasized when attempting to restore anterior arches and toes that have not been crumpled too long.

It is possible to assist bones to resume their normal relationships, also to relieve sometimes undue tensions that have tended to develop as toe joints and medio-tarsal joints have been subjected to harmful strain, with tendencies toward gradual subluxations.

Contracted toes can be gently and gradually straightened; and tendons that move them

may be helped to resume their usual smoothly functioning control. Temporary pads are very important adjuncts to maintain advantages gained between treatments.

(32)—*Shoes that possess inswinging front parts of approved orthopedic style may be excellent for longitudinal arches, and may be harmful simultaneously for weak frontal arches. In such shoes there is shifting of weight more to outer edges of feet and toes. The same direct pressure that is exerted very commonly on the outer toes, deflecting them and producing calluses, while it helps to maintain the longitudinal arch, also thrusts the frontal arch downward. When this condition develops, there should be given more support under longitudinal arches, and shoes fitted which possess sole patterns that conform more closely to imprints of the bare feet. New straighter lasts should be recommended and fitted long, with frontal arch pads temporarily to hold anterior arches.*

Orthopedists agreed, 74=74%; disagreed, 9=9%; doubtful, 10=10%; no opinion, 7=7%.

Shoe dealers agreed, 30=85%; disagreed, 3=9%; doubtful, 1=3%; no opinion, 1=3%.

*Boston, Mass.*—I disapprove entirely of inswinging shoes under any circumstances.

*Philadelphia, Pa.*—There is no piece of leather made that will hold the foot laterally.

*New York City.*—Applies only if the shoes are fitted too short or narrow or both, or if there is marked deformity of the foot.

*Chicago.*—Doubtful whether new straighter lasts should be recommended.

*Winnipeg, Manitoba.*—Galloway - Gibson Clinic: Disagreed.

*Rochester, N. Y.*—Generally correct.

*Worcester, Mass.*—The shoe fitter should not attempt fitting shoe until arch pads are secured.

*Seranton, Pa.*—Dr. E. Sturge: Pads give temporary relief but metal supports are more curative because they are more efficient.

(33)—*Anterior arches that are weakening in natural foot shaped low heeled shoes can be held by new shoes more snugly fitted at the waist of the shoe, or by independent anterior arch cuffs that can be worn in loose shoes. The latter method combines in a single pair of shoes the possibility of easily changeable and variable degrees of support and freedom.*

Orthopedists agreed, 86=86%; disagreed, 3=3%; doubtful, 8=8%; no opinion, 3=3%.

Shoe dealers agreed, 27=77%; disagreed, 3=9%; doubtful, 3=9%; no opinion, 2=6%.

*New York City.*—Dr. Irving D. Steinhardt: Disagreed.

*New York City.*—Anterior arch cuffs will have the tendency to weaken further the muscles and ligaments of the anterior part of the foot.

*San Francisco.*—Shoes snugly fitted at the waist of the shoe are chiblain makers.

*Providence, R. I.*—Dr. Lowman: I should be doubtful in regard to the anterior arch cuff being worn in loose shoes. They are all right if you mean simply symptomatic treatment and not in reference to continuous treatment.

(34)—*Sole patterns of shoes that are to be worn most of the time should agree with imprints of bare feet as the latter are made while sustaining body weight.*

Orthopedists agreed, 79=79%; disagreed, 11=11%; doubtful, 8=8%; no opinion, 2=2%.

Shoe dealers, agreed, 29=83%; disagreed, 2=6%; doubtful, 2=6%; no opinion, 2=6%.

*Hartford, Conn.*—Dr. R. M. Yergason: A swing last for a swing foot but for no other.

*Brooklyn, N. Y.*—Dr. Walter Truslow: Agreed unless correction of deformity is undertaken, in which case shoes should permit correction.

*Nashville, Tenn.*—Dr. R. W. Billington: Applies only in case of feet of normal shape and attitude. Otherwise they should be more or less corrective in shape.

*Denver, Colo.*—Dr. R. G. Packard: Doubtful.

*Muskegon, Mich.*—A sole print of a deformed foot is not necessarily a good pattern for a shoe. Any shoe made to fit a deformed foot must be necessarily incorrect.

(35)—*Sole patterns of flexible shoes often exhibit extreme inward curving of their anterior parts, tending to over-correct longi-*

*tudinal arches, and this is a benefit in some instances.*

Orthopedists agreed, 72=72%; disagreed, 19=19%; doubtful, 6=6%; no opinion, 3=3%.

Shoe dealers agreed, 17=48%; disagreed, 4=11%; doubtful, 8=23%; no opinion, 6=17%.

*Boston, Mass.*—I do not believe that the foot follows the shoe.

*Portland, Ore.*—Dr. Chas. R. McClure: Disagreed.

*New Orleans, La.*—Dr. Hatch: Doubtful.

*Chicago, Ill.*—I do not believe that flexible shoes correct arches much by their shape.

*Boston, Mass.*—Such shoes are good only for a very few inswinging feet.

(36)—*Flexible shoes should be made also with less extreme inward swinging of front parts, because there are many deformed and very serviceable feet that fit more perfectly in straighter lasts. Many such feet will never attain postures demanded by the most extreme inswinging shoe shapes.*

Orthopedists agreed, 90=90%; disagreed, 5=5%; doubtful, 1=1%; no opinion, 4=4%.

Shoe dealers agreed, 28=80%; disagreed, 1=3%; doubtful, 2=6%; no opinion, 4=11%.

*San Francisco, Calif.*—Flexible shoes never should be made with heels on them at all.

*Rochester, N. Y.*—Flexible shoes may be wrong, and it is impossible to do a correct job with wrong shoes.

*New Orleans, La.*—Dr. H. Theodore Simon: I am much opposed to flexible shanked shoes and also plates on the order of Whitman plates. I have found that shoe alterations, preferably the Ridlon wedge—in conjunction with extra heavy shanks in certain cases—give entire satisfaction.

(37)—*Heels should be low and broad for men's wear and of similar shape and height for women's shoes, or perhaps even a trifle higher for women's ordinary wear. Heel heights illustrate an instance of foot adaptability. Heels have been worn so universally and for so long that the primitive heelless condition has become less natural for most people. Foot efficiency theoretically may have diminished a trifle, but it cannot be measured or appreciated in low broad heels with broad bearing surfaces. For modern existence, it would be hard to disprove that heels are not an improvement over less desirable barefooted posture.*

Orthopedists agreed, 89=89%; disagreed, 3=3%; doubtful, 6=6%; no opinion, 2=2%.

Shoe dealers agreed, 31=88%; disagreed, 1=3%; doubtful, 0=0%; no opinion, 3=9%.

*Chicago, Ill.*—Dr. John Ridlon: The height of heel should be determined by the degree of possible dorsal flexion of the foot.

*New York City.*—Dr. Dexter D. Ashley: The idea that heels have been worn so universally and for so long that the primitive heelless condition has become less natural for most people, is to my mind a far fetched one. The child and early adolescent is still a plantigrade. No evolution is perceptible. Thus at 13 years there is a transmutation, a demand for high heels. The short heel cord is evident only after some years of high heels. Heel heights illustrate an instance of foot adaptability to abnormal position of weight bearing. Primitive man walked on the soft ground. Hard sidewalks and floors and much standing today demanded in the walks of life necessitate a heel.

Did you, "the barefoot boy with cheek of tan," have metatarsalgia? No.

*Rochester, N. Y.*—Best argument for shoes with stiff shanks to preserve arches.

*Spokane, Wash.*—Dr. C. F. Eikenbary: Doubtful.

*Lynn, Mass.*—Everett H. Dunbar: Heels should be made to harmonize with longitudinal arches. An arch with only one-eighth inch elevation at its highest point may be perfectly normal, and all bones may bear evenly on their articular facets. Not much elevation at the heel should be attempted with this type. Longitudinal arches of other feet may have a different curve with three-quarter inch elevation at their highest points, and higher heels are required in this latter type to give a comfortable poise. The natural curve of the longitudinal arch should be carefully considered in every individual case; and, when the right elevation of heel is discovered there

should be no deviation made from this level. *Philadelphia, Pa.*—About 15 per cent of men and 30 per cent of women have short heel tendons and must wear higher heels.

*Los Angeles, Calif.*—Dr. Walter C. S. Koenig: Heels may be too low as well as too high.

(33)—*Continuous wear of very high heeled, pointed toed shoes that are fitted also continuously too tightly and too short, should be condemned very strongly on every possible occasion. The majority of foot deformities originate in this manner among young girls, and are continued among women who choose fashionable crippling styles for continuous wear without change.*

Orthopedists agreed, 100=100%; disagreed, 0=0%; doubtful, 0=0%; no opinion, 0=0%.

Shoe dealers agreed, 35=100%; disagreed, 0=0%; doubtful, 0=0%; no opinion, 0=0%.

*Des Moines, Ia.*—A. N. Canfield, Elvenfield Shoe Company: Ninety per cent of all foot trouble is caused by misfitted shoes, and wrong types of shoes. More foot troubles can be eliminated by proper fitting of right types of shoes than by all other remedies.

*Memphis, Tenn.*—Shoes that are too short will cause trouble regardless of shapes.

(39)—*The public should be protected against most dangerous varieties of shoes as they are protected against harmful foods and drugs, but manufacturers of fashionable shoe should not be held responsible for foolishness of some customers who wear them indiscreetly.*

Orthopedists agreed, 81=81%; disagreed, 9=9%; doubtful, 7=7%; no opinion, 3=3%.

Shoe dealers agreed, 29=83%; disagreed, 5=14%; doubtful, 1=3%; no opinion, 0=0%.

*Boston, Mass.*—The public should be advised but not forced.

*Boston, Mass.*—H. E. Hagan: Disagreed.

*Memphis, Tenn.*—Disagreed. Common sense is the only cure. *Caradine Shoe Co.*

*Austin, Texas.*—Disagreed. E. M. Searlough & Sons.

*Des Moines, Iowa.*—The salesman can help to protect the public, and can get their appreciation. A. N. Canfield.

*Wheeling, W. Va.*—Disagreed with first sentence. Agreed with second sentence.

*Iowa City, Iowa.*—W. H. M. Stewart: Agreed.

*Denver, Colo.*—Robt. H. Johnston: Disagreed.

*Dodge City, Kan.*—H. E. Ripple: Agreed.

*Narfolk, Va.*—Marc Gray, Hofheimers Brothers Company: Agreed.

*Moline, Ill.*—Leo S. Waynes, Waynes Brothers: Agreed.

*Memphis, Tenn.*—Zellner Shoe Company: Agreed.

*Indianapolis, Ind.*—Dr. H. R. Allen: If the purpose is to put better shoes on the market then information should be given to the manufacturer pertaining to orthopedic shoe construction, and reasons for such different construction.

*Milwaukee, Wis.*—To what extent are we "our brother's keeper"?

(40)—*A caution might be stamped on certain shoes to advantage as follows: "These shoes are recommended highly for evening wear, but they may injure the feet if worn continuously."*

Orthopedists agreed, 80=80%; disagreed, 7=7%; doubtful, 1=1%; no opinion, 6=6%.

Shoe dealers agreed, 21=60%; disagreed, 9=26%; doubtful, 4=11%; no opinion, 2=6%.

*New Haven, Conn.*—Sydney Stores: Disagreed.

*Boston, Mass.*—Disagreed.

*Chanute, Kans.*—Disagreed.

*Memphis, Tenn.*—Disagreed. A caution on shoes to "stop, look, and listen" would have equal effect. Style is the Kaiser.

*Atlanta, Ga.*—R. A. Rankin, Foot Expert for Fred S. Stewart Company: Agreed.

*Lewiston, Me.*—J. J. Curran: Agreed.

*Iowa City, Ia.*—W. H. Stewart: Doubtful.

*Chicago, Ill.*—Dr. Chas. A. Parker: It would be foolish.

*Philadelphia, Pa.*—Instead of saying "these shoes are highly recommended," say "may be worn." There is absolutely nothing but vanity to recommend them.

*Los Angeles, Cal.*—Dr. Lowman: I entirely disagree that we should give any recommendation whatever to any shoe which is not properly shaped, for evening wear, or any other time. It seems to me too much like side stepping, and taking a position of a flexible conscience, rather than being absolutely definite in our surgical demands.

*Boston, Mass.*—Manufacturers would disagree to such a plan because it would tend to diminish sales, and manufacturers are in business to make as many shoes as they can.

(41)—*A definite arbitrary standard might be established profitably, and shoes that exceed this limit should be looked on with suspicion unless their special uses are clearly defined. Perhaps some such scheme might*

*tend to discourage the invention of least desirable styles.*

Orthopedists agreed, 82=82%; disagreed, 5=5%; doubtful, 6=6%; no opinion, 7=7%.

Shoe dealers agreed, 22=63%; disagreed, 6=17%; doubtful, 4=11%; no opinion, 3=9%.

*Philadelphia, Pa.*—Utopia, not practical.

*Rochester, N. Y.*—Caution would be advisable.

(42)—*Shoe retailers are obliged to cater to the demands of the public to a very important degree, yet they can influence opinions of thoughtful customers to an important degree if they wish, and should use means in their power to improve styles of shoes worn.*

Orthopedists agreed, 95=95%; disagreed, 2=2%; doubtful, 0=0%; no opinion, 3=3%.

Shoe dealers agreed, 33=94%; disagreed, 0=0%; doubtful, 1=3%; no opinion, 1=3%.

*Dayton, Ohio.*—I believe that you will receive no co-operation worth while in its extent from shoe dealers, especially those catering to working classes.—The Fred Hageman and Sons Company.

*Portland, Me.*—T. O. Vanamee: The greatest faults I find in the commercial fitting of shoes are, lack of understanding of the fitters, too high heels, short shoes from heel to ball, outflare toes.

*Memphis, Tenn.*—The shoe man cannot act as guardian for all customers. He cannot render the services required of a doctor whose skill goes beyond appearances. However, shoes properly fitted can give relief to many of the foot troubles, and this is sadly disregarded by many who buy as well as those who sell.

*Boston, Mass.*—Retailers are the chief sinners, not the public.

*Boston, Mass.*—Dr. H. W. Marshall: One important strategic point for influencing the public is the shoe store. Nearly everyone must pass this point, and those customers who are interested should be given easy means of learning about their shoes and feet. Manufacturers prepare booklets, describing their special lines, for retailers to distribute. Why not prepare a brief explanation of facts in a comprehensive, impartial way? Would it not stimulate interest of customers, benefiting reputations and sales of shoe dealers, and perhaps induce customers to consult physicians more frequently? The business of selling shoes would demand that cost of such pamphlets should be very small in order not to exceed profits accruing from them.

I made an experiment of collecting ideas and illustrations that were put into final form suitable for shoe fitters and customers by the editor of the *Foot and Shoe Recorder*, then published in that trade journal. There were no applications for reprints. I am told, although the latter would be furnished to shoe dealers by the *Recorder*, which journal is devoted to welfare and advancement of the shoe trade.

I do not believe that the public should be subjected now to much more special shoe education except on request. Let those retailers who are progressive have convenient means of enlightening thoughtful customers. Orthopedists perhaps can exert the greatest influence by agreeing as fully as possible among themselves, thus increasing the value of medical opinion in the minds of the shoe merchants and the public.

(43)—*Rigid feet, fixed more or less in restricted postures, are commonly a result of abnormal adhesions between opposed movable joint surfaces in the feet, or of adhesions between tendons and smooth sheaths in which they slip normally, or of delicate inelastic fibers that form among muscles and their coverings during inflammatory processes.*

Orthopedists agreed, 96=96%; disagreed, 0=0%; doubtful, 4=4%; no opinion, 0=0%.

Shoe dealers agreed, 29=83%; disagreed, 0=0%; doubtful, 2=6%; no opinion, 4=11%.

(44)—*Underlying causes of foot rigidity therefore usually are inflammatory processes in the tissues. Inflammatory processes, in turn, are commonly caused by bacteria or their products of growth which gain entrance to circulating blood and which then exert a harmful influence as bacteria lodge and grow in foot tissues, or as their circulating products pass through feet and irritate them in passing. Let it be explained in a general way that bacteria and their products get into circulation often during acute contagious fevers, during blood poisoning, or from some spot of chronic infection containing bacteria somewhere in the body.*

Orthopedists agreed, 84=84%; disagreed, 1=1%; doubtful, 10=10%; no opinion, 2=2%.

Shoe dealers agreed, 19=51%; disagreed, 2=6%; doubtful, 2=6%; no opinion, 12=34%.

*St. Louis, Mo.*—Causes of foot rigidity are often traumatic ones.

*Nashville, Tenn.*—Dr. Billington: I agree

except that I believe there is a considerable proportion of cases where stiffness is due to sensitive ligaments caused by strain producing muscle spasm without any infectious element.

*Worcester, Mass.*—Dr. Kendall Emerson: As used, term may refer to active or passive congestion. I should consider this the cause rather than bacterial infection in cases being discussed. Certain bacterial infections cause certain cases of rigidity. Should you argue a universal infective cause for rigid feet?

(45)—*Feet are both weak and rigid in some instances. Shoe fitters will save their customers much trouble, and save good reputations of their chief if they refer such persons promptly to orthopedic surgeons.*

Orthopedists agreed, 99=99%; disagreed, 0=0%; doubtful, 0=0%.

Shoe dealers agreed, 31=88%; disagreed, 1=3%; no opinion, 3=9%; doubtful, 0=0%.

*San Francisco, Cal.*—I think people generally seek proper advice.

*Greensburg, Ind.*—Take Dr. Scholl's course and fit them with corrective appliances. Beats the doctor's advice.

*Des Moines, Ia.*—Or study these cases themselves so they will be able to give them best advice.

*San Francisco, Cal.*—Dr. H. L. Langnecker: Agreed.

*Milwaukee, Wis.*—What can the surgeons do?

(46)—*Best shoes obtainable will not relieve these conditions satisfactorily alone. Feet may have to be immobilized during acute inflammatory stages in most desirable postures, or subjected later to various combinations of passive exercises, active exercises, manipulations, massage, and physical therapy to restore them.*

Orthopedists agreed, 99=99%; disagreed, 1=1%; doubtful, 0=0%; no opinion, 0=0%.

Shoe dealers agreed, 32=91%; disagreed, 0=0%; doubtful, 1=3%; no opinion, 2=6%.

*Memphis, Tenn.*—Shoe fitters can only give relief when the foot is restricted by outside pressure.

*Milwaukee, Wis.*—S. J. Brouwer: I believe that it would be a good thing if the orthopedic surgeons would demonstrate to the shoe retailer just what these are, in order that he may get his shoe customer interested in having the orthopedic surgeon do these things for him. We certainly have not the time in a busy shoe store to go through all the processes mentioned. We could send far more customers to the orthopedic surgeons if they would teach us how to diagnose our customers and talk more intelligently, so that they would be willing to go to an orthopedic surgeon.

(47)—*Blisters, corns, calluses are very common and troublesome results of mechanical irritation from improperly fitted shoes, or improper use of proper shoes. Prevention of these troubles is the best procedure.*

Orthopedists agreed, 99=99%; disagreed, 1=1%; doubtful, 0=0%; no opinion, 0=0%.

Shoe dealers agreed, 35=100%; disagreed, 0=0%; doubtful, 0=0%; no opinion, 0=0%.

*Des Moines, Ia.*—Dr. W. J. Fenton: Improperly fitting hose play a very important role in causation of these troubles. Hose often shrink in washing and become too tight.

*Boston, Mass.*—Removal of offending pressure is the best remedy.

*San Francisco, Cal.*—Tips or caps on shoes are corn cultivators. All tips and boxes should be dispensed with.

(48)—*Bunions, with accompanying deflections of great toes, are results of improper shoes and are very common, but deflections of toes may result also from so-called rheumatic diseases, or from bone disease of other nature.*

Orthopedists agreed, 99=99%; disagreed, 0=0%; doubtful, 1=1%; no opinion, 0=0%.

Shoe dealers agreed, 33=94%; disagreed, 1=3%; doubtful, 0=0%; no opinion, 1=3%.

*San Francisco, Cal.*—Dr. Leonard W. Ely: Bunions are the result of hallux valgus, and this is congenital.

*San Diego, Cal.*—Dr. M. C. Harding: Bunions are rarely due to shoes alone.

*Muskegon, Mich.*—Bunions may be the result of improperly shaped shoes, but more often come from pointed-toe hosiery. For a foot held in a pointed bag can get very little benefit from the most perfectly shaped shoe, as the bag inside the shoe is cramping the toes together. I find that pointed-toe hosiery produces more bunions than rheumatism or other diseases.

(49)—*Bunions can be relieved many times by a change of shoes. In bad chronic cases surgical treatment is advisable and yields excellent results.*

Orthopedists agreed, 95=95%; disagreed, 1=1%; doubtful, 4=11%; no opinion, 0=0%.

Shoe dealers agreed, 28=80%; disagreed, 2=6%; doubtful, 3=9%; no opinion, 2=6%.

*Boston, Mass.*—Bunions can be relieved many times by use of proper shield to relieve pressure and to prevent irritation.

\*Hutchinson, Kan.—Cannot always be relieved by changing shoes.

\*Muskegon, Mich.—I would suggest that surgical treatment for any bunion is unnecessary, as I have yet to find a case which will not respond to the proper kind of exercises, provided the patient is under forty years of age.

Chicago, Ill.—Dr. B. H. Monk: Do not believe a real bunion or real hallux valgus is relieved by shoes. It is possible to relieve a tendency that way, but not a really developed one.

Philadelphia, Pa.—Operation is the only cure for established cases.

(50)—Diseases of bones, fractures of bones, paralysis of muscles, shortening of tendons with marked contractures and deformities all frequently need surgical care.

Orthopedists agreed, 100=100%; disagreed, 0=0%; doubtful, 0=0%; no opinion, 0=0%.

Shoe dealers agreed, 35=100%; disagreed, 0=0%; doubtful, 0=0%; no opinion, 0=0%.

New York City.—Dr. Henry Keller: Conservative treatment should be given a thorough trial, however, before operative procedures are instituted; as many cases are worse after operation than before.

These collected ideas require considerable effort to read through carefully. Larger numbers might exceed limits of patience of readers, and, with an overwhelming number, decision that each individual case must be handled in strictly individual manner would soon be reached.

Among the total five thousand points voted on by one hundred orthopedists, fifty to each person, there were in all 4,413 points of agreement, 272 points of disagreement, and 315 points of doubt or no opinion. These figures represent 88 per cent of agreement, 5 per cent of disagreement, and 7 per cent of doubtful points or points not voted on.

For the 1750 total points among thirty-five shoe men there were 82 per cent of agreement, 7 per cent of disagreement, and 11 per cent of other indeterminate points.

Matters agreed on often are dismissed quickly from mind, while disagreements are retained most clearly sometimes to disproportionate degrees as the result of controversies. It is of interest therefore to observe how well agreed orthopedists and shoe men may be when it comes to a vote, despite many confusing comments.

The familiar story of the group of blind men who examined an elephant can be recalled profitably. Each selected a different part; one examined the trunk, another the tail, a third the elephant's side, and so on. In the discussion that followed, complete disagreement was possible, although each examiner was correct within his limited sphere. The point to be emphasized is that controversies in that instance were wholly unjustified. There were no legitimate grounds for arguments. All data needed to be fitted together and retained.

Disagreements about many orthopedic subjects can be included in this class. Disagreements between shoe men and orthopedists to a considerable extent are of such nature.

Partisan viewpoints constitute a second important source for disagreements. A maker or seller of a special type of shoes dwells especially on merits of his particular lines. He may notice shoes of different types for comparisons of disadvantages of the latter with advantages of his own special kinds. An orthopedic surgeon may become absorbed in determining the benefits of surgery alone, and he may compare his successes with failures of non-operative methods. Such perfectly legitimate one-sided views abound, but, as they increase in numbers, they become responsible also for apparently never-ending controversies. A period of deliberation and re-adjustment now is becoming an increasing need.

Hope of restoration of order and of obtaining clear, accurate, general conceptions of confusing details concerning feet, lies increasingly in impartial fair comparisons—merits with merits, disadvantages with disadvantages, also in collection of all permanent facts and in fitting each into its proper place in the whole picture.

If such labors are not undertaken, then accumulated knowledge may become a hindrance rather than an advantage. Patients may receive increasingly poor treatment at times possibly while numbers of special methods and ideas continue to increase. All important regions of the body, it seems, should be surveyed in the same impartial, comprehensive way if orthopedic surgery is to progress in well balanced manner.

One way of reasoning is that, because one special type of shoes or one orthopedic method is good, others are bad. Instead, should there not be recognition that all methods or types have some object in their existence, and possess some advantages and some limitations of various sorts? Let it be remembered, too, that even very trivial advantages or disadvantages occupy positions of deciding importance occasionally under exceptional circumstances.

After looking over the scope of foot troubles, the need of renewed study of a few fundamental principles of muscle physiology especially, and of the physiology of other foot structures, becomes apparent. Shoe fitters should realize for the sake of their customers and their own ultimate welfare that they are not physicians. Physicians ought to realize that they do not know all details of shoe fitting. Each should keep within their own sphere of activity generally, with perhaps occasional exceptions. Yet each should learn as much as possible of the

other's viewpoints for closest cooperation. Best shoe retailers should receive support most strongly of the medical profession, and vice versa.

There is good evidence now for accepting the majority of ideas that have been advanced concerning shoes and feet, with their advantages and limitations. Relief for weakened muscles is possible by means of foot plates, pads, strappings, improved foot postures that are assisted by certain shoes, special supporting heels, and some carefully designed and properly fitted shoes possessing reinforced shanks. The special type of support has to be selected according to individual needs and special limiting circumstances.

Weakening muscles can be relieved at times by hygienic measures that increase nerve tone and reduce vascular defects.

Too much and too continuous support must be avoided. Muscles can be improved by increased functional use, flexible shoes, special exercises, massage, and physical therapeutic means, each individual case responding best to individual care.

Corrections of deformities may be attempted at times by manipulations, exercises, strappings, appliances, casts, surgery, and by shoes themselves. Changes from bad shoes to those that allow contracted feet to expand naturally are important factors in foot corrections many times.

There are four main channels only through which influences acting on the feet possibly can exert themselves. These are through mechanical effects of functional use and support of body weight; secondly, through all external means including shoes; thirdly, through the circulating blood; and lastly, through controlling nerves. These four main groups of influences always should be considered in every individual case, for they all act in combination under normal conditions.

Responsibility for success or failure in treatment should not rest on particular types of shoes or medical measures primarily, but on persons who advise them. The agents or methods will be all right when they are used correctly for their intended purposes. Wearers of shoes themselves very frequently indeed are at fault. A real service in this field has been rendered by those orthopedists and shoe men who have made this survey possible, over one-third of the orthopedists and over one-ninth of all shoe men having responded to the questionnaires that were sent out. Acknowledgement of this service is hereby made.

# A Circular Outdoor Pool

**T**O supply its citizens with healthful bathing facilities the city of Johnstown, Pa., last year constructed a circular swimming pool at a total cost of \$24,932. The pool is located on land owned by the School Board and is part of a recreation center which when developed will contain a baseball diamond, tennis courts, and playground.

The oval type of pool constructed is described by H. Lee Wilson, City En-

gineer of Johnstown in *The American City*. The circular type of pool with graduated beach has proved particularly satisfactory for a public pool as the shallow water affords room for those who do not swim. A diving board at the center gives open space for the swimmers. The pool is 252 feet long and 165 feet wide, with a capacity of one million gallons. It

accommodates over one thousand bathers at one time. The water depth at the center is ten feet gradually decreasing to only 15 inches at the edge. At a point 54 feet 6 inches from the edge there is a precipitate increase in the depth from 6 to 9 feet, thus giving ample depth for diving from the platform.

The floor of the pool is 6 inches thick reinforced with steel wire mesh weighing 35 pounds to the 100 square

side and the outside faces. A 9-foot concrete sidewalk, 6 inches thick, has been placed entirely around the pool. The walk slopes away from the pool, one-fourth inch to the foot, and this prevents surface filth from entering the pool. It is planned to build bathhouses, plans for which are now being drawn in connection with other improvements.

Drainage is by means of a main drain to an outlet under the center

Plans showing the expansion joints, longitudinal section, and steel mesh reinforcement of the new Johnstown, Pa., swimming pool.

gineer of Johnstown in *The American City*. The circular type of pool with graduated beach has proved particularly satisfactory for a public pool as the shallow water affords room for those who do not swim. A diving board at the center gives open space for the swimmers. The pool is 252 feet long and 165 feet wide, with a capacity of one million gallons. It

feet. The side walls are 12 inches at the top and 18 inches at the bottom, providing a batter on the inside face to offset ice expansion when the water is allowed to freeze for skating. The reinforcement is continuous from floor to wall, and the walls are additionally reinforced by 1-inch steel rods placed vertically 6 inches apart, and by three 1-inch horizontal rods at both the in-

of the pool which carries the water to a 12-inch sanitary sewer. A concrete sump prevents the overloading of this sewer which is only a temporary connection, the permanent connection to be made as soon as the construction of the new 36-inch concrete storm sewer is completed.

The water for the pool is supplied from two distinct sources, the main

The pool as it looks today completed. The floor of the pool gradually slopes toward the center where it is deep enough for diving.

supply coming from one 8-inch driven well which assures pure water, and a subsidiary supply coming from the city water supply. The water is supplied at a point in the floor near the center of the pool through a 24-inch pipe line which empties into the sewer

in the same manner as the drainage system.

The final cost of the pool was as follows:

700 tons of blast furnace slag, delivered .....	\$ 1,400
500 tons of river sand, delivered.....	1,700
1,000 barrels of cement, delivered.....	4,000
1,764 lineal feet of drain tile, delivered	352

184 lineal feet cast iron pipe and valve, delivered .....	1,700
12,000 pounds of steel reinforcing mesh, delivered .....	450
5,000 pounds of steel reinforcing rods, delivered .....	200
Rent on mixer, 60 days at \$10.....	600
Labor .....	11,500
Miscellaneous, expansion joints, form lumber, tools, etc.....	3,000
Total .....	\$24,932

## Pay of Medical Personnel

**A**FTER having passed the House and Senate and having been satisfactorily adjusted in conference the measure having to do with the pay of army, navy, and public health service medical officials was sent to the White House June 7 for the President's signature. The bill as passed is said to meet with the approval of the commissioned personnel of the U. S. Public Health Service as well as with the medical officers of the army and navy. The pay rate set forth in the act is as follows:

Assistant Surgeon General (Colonel) over 26 years' service, \$4,000; first appointment above captain, \$4,000; appointed under Sec. 24, Act June 4, 1920, \$4,000; less than 26 years' service, \$3,500.

Senior Surgeon (Lieutenant Colonel) over 30 years' service, \$4,000; over 20 and less than 30 years, \$3,500; first appointment above second lieutenant, \$3,500; appointed under Sec. 24, Act June 4, 1920, \$3,500; less than 20 years' service, \$3,000;

Surgeon (Major) over 23 years' service, \$3,500; over 14 and less than 23 years', \$3,000; First appointment above second lieutenant \$3,000; appointed under Sec. 24, Act June 4, 1920, \$3,000; less than 14 years' \$2,400.

Past Assistant Surgeon (Captain) over 17 years' service, \$3,000; over 17 and less than 17 years', \$2,400; first appointment above second lieutenant, \$2,400; present rank July 1, 1920, or earlier, \$2,400; less than 7 years', \$2,000.

Assistant Surgeon (First Lieutenant) over 10 years' service, \$2,400;

over 3 and less than 10 years', \$2,000; first appointment above second lieutenant \$2,000; less than 3 years' \$1,500.

In addition to this base pay there are also rental and ration allowances. These vary according to whether the officer has dependents. The sum for rental ranges from \$480 a year for an assistant surgeon to \$1,440 a year for an assistant surgeon general. The sum allowed for rations is \$237.25 a year for one ration. The allowance for subsistence is based upon the cost of food in the calendar year 1922 from statistical estimates furnished to the President by the Secretary of Labor. If the cost of food in subsequent years should be reduced, the allowance for subsistence will be accordingly reduced. There is also an increase for length of service in the grade.

Nurses' pay is set forth in Section 13 of the Wadsworth-McKenzie bill which passed the House on May 12, 1922 and the Senate on May 22, 1922, was considered in conference, agreed upon, and signed by the President. The act took effect on July 1, 1922. The act provides the following annual rates of pay for Army and Navy nurses: Members of the Nurse Corps of the Public Health Service are not affected by this act:

First three years service, \$840; Second three years service \$1,080; Third three years service, \$1,380; from tenth year on, \$1,560.

In addition to their pay as nurses, superintendents of nurses receive a money allowance of \$250 a year; assistant superintendents, directors, and assistant directors, \$1,500 a year; and

chief nurses, \$600 a year. Nurses are also allowed 60 cents a day for subsistence, \$20 a month for rental, the same as certain officers.

The Lehlbach-Sterling bill provides for reclassification of all civilian government employees. The bill passed the House on December 15, 1921 and was reported in the Senate on February 3, 1922 with several important amendments, some of which directly concerned nurses. In the bill as originally drawn, nurses were included with housekeepers under the Institutional Service. The Senate eliminated this service entirely and placed nursing in the Professional and Scientific, and Subprofessional services. In the former service, there are six grades with compensation ranging from \$1,800 a year to \$7,200, depending upon the type of work performed, the amount of responsibility, and other factors. Salaries in the Sub-professional Service are from \$1,020 to \$3,180 a year, divided into six grades. The nurses of the Public Health Service would be governed by this salary schedule.

A Vocational Guidance Bureau was created in June, 1920, under the management of a council which includes delegates of the ministries of Social Assistance, Education, Commerce and Industry, and Agriculture, together with representatives of various committees, industrial councils, and chambers of commerce. Conferences were held to interest the public and enlist helpers. Data about working conditions and the requirements of the various occupations have been collected.

# A Decade's Progress Against Tuberculosis

## New York City Has Reduced Its Death Rate from Tuberculosis by 51 Per Cent

By GODIAS J. DROLET, STATISTICIAN, NEW YORK TUBERCULOSIS ASSOCIATION, NEW YORK CITY

**T**UBERCULOSIS has developed in almost direct proportion with the increase of humankind over the earth, with the abandoning of living in open air and sunlight and concentrating in towns and cities. Of all parts of the world where mankind teems most densely, New York City offers probably the best illustration. The result has been a staggering toll taken by the "Captain of the Men of Death." In New York, during the twelve years from 1910 to 1921 alone, the number of its victims known to have been taken has totalled 112,316.

City life with its congestion of population, its insufficiency of air and sunlight, its greater distance from fresh food supplies, its feverish activity, its waste of hours of daily travel by working people in addition to their day's toil, its thousands of human contacts in public conveyances with numberless opportunities for the spread of respiratory infection, has brought about a powerful combination tending to reduce resistance against disease and especially tuberculosis which is practically non-existent in country life. And yet, despite these handicaps, a marvelous advance against tuberculosis has been achieved in New York City which gives hope that the disease may either be eradicated as an important cause of mortality or eventually be reduced to a benign infection.

In 1910 tuberculosis in all its forms caused 10,074 deaths in New York, the death rate of that year having been 210 for each 100,000 inhabitants. In 1921, even though the city had increased by a million population to 5,751,859 inhabitants, the total number of deaths from tuberculosis was 5,922; the death rate being, therefore, in the last year, 103 for each 100,000 people. The death rate of 1921 was only one-half that of 1910, the exact reduction in mortality being 51 per cent. If the death rate of last year had been the same as that which prevailed in 1910, the total number of deaths would have been 12,079 instead of the 5,922 which occurred.

It must be admitted that in any population the general death rate from all causes may vary in different proportions than the tuberculosis

death rate since a number of diseases have different evolutions, or, by scientific discoveries, as in the case of smallpox or diphtheria, they may even be practically wiped out. It is, therefore, all the more interesting to note that in New York tuberculosis has been reduced to an even greater extent than the general mortality though in the latter there have been remarkable reductions. In 1910 the general death rate in New York from all causes was 16 for every thousand inhabitants. In 1921 it was only a little over 11 for each thousand. The reduction in the general death rate during the past twelve years, therefore, has been 31 per cent whereas the tuberculosis death rate has decreased by 51 per cent.

### Prevalence in New York

The detailed figures of tuberculosis mortality in New York City since 1910 are given in Table I, and the course of the death rate is graphically illustrated in the accompanying Diagram No. 1. Looking over the details for each year it is interesting to note, first, that up to 1918 the annual number of deaths averaged about 10,000; second, that the low level of 6,000 deaths a year has now been reached, despite the interruptions of the war and of the influenza epidemic of 1917 and 1918; third, that up to 1916 the death rate from tuberculosis other

than pulmonary, such as gland, bone and meningeal forms, which are mostly confined to children, was practically constant between 27 and 30 for each 100,000 inhabitants, but that thereafter it quickly dropped to 13.5. Tuberculosis of the latter forms in children results largely from a bovine source of infection. It is probable that the general pasteurization of milk, enforced in New York City since 1915, has been, among other factors, very important in accelerating the decline registered in 1921 when the rate was only half what it was in 1915.

It has always been maintained by anti-tuberculosis workers that the progress of the fight against the disease should be registered to its largest extent among children, since they, more than other groups of the population, react more readily to infection. In New York City the total number of deaths of children under fifteen years of age from all forms of tuberculosis was 1,199 in 1910, whereas in 1921 it was only 574. This reduction in the absolute number of deaths among children had occurred in the face of an increase in the total number of children of that age of almost 50 per cent. It is therefore evident that the death rate among children exposed has fallen even faster than among adults.

\*Bulletin, New York Tuberculosis Association, January, 1922.

\*TABLE I.—NEW YORK CITY TUBERCULOSIS MORTALITY, 1910 to 1921

Year	Number of Tuberculosis Deaths			Rate per 100,000 Population		
	Pul-monary	Other Forms	All Forms	Pul-monary	Other Forms	All Forms
1910	8,692	1,382	10,074	181	29	210

 April 15, 1910.....4,766,883  
 January 1, 1920.....5,620,048

RATES DURING INTERCENSUS YEARS are based upon the estimated mid-year populations, according to arithmetical progression.

Diagram I.

Another interesting fact that concerns tuberculosis in New York is that the disease is being conquered more rapidly than in the rest of the country. A comparison of its course in New York and in the United States registration area, which now includes approximately 87,000,000 people, is shown in Diagram No. 2; the detailed mortality figures being given in Table II. It will be seen that the death rate of New York exceeded in 1910 that of the United States area which also contains groups under the favorable conditions of rural life by 31 per cent. In 1920 the excess of the city rate over that of the United States was only 11 per cent. The tuberculosis cloud hanging over New York has, therefore, steadily decreased. Figures for 1921 for the entire United States are not yet available; but with the

continued decrease in the city, it is probable that the two rates may now be equal.

What are the resources and methods which New York has marshalled and utilized for its fight against the tubercle bacillus? First, let us say that a community, like any other living organism, responds or reacts in relation to the degree or extent of stimulus acting upon it. In studying the specific anti-tuberculosis measures of New York City, a consideration of its local difficulties and necessities will better explain the organization. New York, though mentioned under one name is far from being a homogeneous community. While it contains in Manhattan the most congested tenement and business life, it

\*All forms.

also includes in its outlying boroughs of Queens and Richmond distinctly rural districts where sections of the city's population, far removed from medical and social conveniences, are left much to themselves for their battle against disease. Then again in its racial composition New York City contains a strange collection of nationalities. It has received and is attempting to assimilate more than one million Jews from some of the poorest parts of Europe. It has an Italian population estimated at 500,000, making it one of the largest Italian cities of the world. New York also includes 175,000 colored people, with all their susceptibility to tuberculosis, especially under conditions of northern city life. Finally, racial groups, like the Irish and those recently coming from agricultural parts of the world or from the country in America, have come to face the city's congestion and conditions with all their greater susceptibility to the development of tuberculosis as compared with city-dwelling stock. Most of the above groups are of recent arrival and have been thrown into the melting pot under conditions often involving great hardships in their readjustment to city life and they furnish an easier prey to tuberculosis than the native stock.

Local Measures and Agencies

With the preceding composite picture of New York in mind, it is easier to understand the variety and number of institutions that have been found necessary to fight so ubiquitous a foe as tuberculosis in so large and diversified a community. No single agency has been found sufficient though many common objectives in the organizations have been developed.

First among the measures utilized by New York against tuberculosis must be mentioned the remarkable Sanitary Code which the city has created for its protection. This is constantly being strengthened by the Board of Health and its Advisory Council. The foundation for health work which it has laid has served as a model for many other communities. The local Sanitary Code requires not only registration of tuberculosis but has been followed by sanitary supervision, from the time of the discovery of cases to their final disposal. The Department of Health, besides furnishing laboratory facilities for the examination of sputa, also operates the large Municipal Sanatorium at Otisville, in Orange County, with 575 beds, and Riverside Hospital, with 225 beds. It also maintains nineteen tu-

berculosis clinics in various parts of the city. Not only does it watch carefully over the enforcement of the registration enactment, but it follows up for sanitary supervision and instruction every case that is not under the care of a clinic, physician, or hospital, thus limiting infection and protecting the community. The cases followed for sanitary supervision, known as "at home" cases, have been as many as 10,000 on certain days of the year. To them the Department of Health sends visiting nurses, and occasionally even medical inspectors. In this type of home work the Department of Health has paid since 1910 no less than 1,100,000 calls.

The Department of Public Welfare of New York City maintains the large tuberculosis hospitals, Sea View and Metropolitan, in addition to subsidizing a number of beds in private hospitals for the care of the tuberculous in different parts of the city. An average of 3,000 beds have thus been filled daily by tuberculous patients receiving proper care and removed from the danger of infecting their families.

In addition to the municipal sanatorium, New York State reserves about 125 beds for city patients in the State institution in the Adirondack Mountains.

There are also in New York, covering the entire city, the special tuberculosis dispensaries, members of the Association of Tuberculosis Clinics, which, as stated above, include nineteen clinics of the Department of Health, four of the City Department of Bellevue and Allied Hospitals, and eight others maintained by private hospitals or health agencies. All these clinics have banded together for the thorough covering of the city with a follow up system of care and instruction in the home of every tuberculosis patient coming to them for treatment. More than forty thousand people, one-half of whom are children, were kept under the care and observation of these clinics in 1921 alone. Since 1910 they have examined nearly 200,000 members of the community, securing in most of them some improvement and correction of physical defects in addition to caring for the tuberculous. Visiting nurses from these clinics pay from sixty thousand to seventy-five thousand calls annually to the homes of patients and their families. This service is in addition to the sanitary follow-up of the Department of Health for the "at home" cases, the clinics confining their visiting to the clinic patients. The type of instruction given by clinic nurses is unique,

Diagram II.

It is based upon actual knowledge of home conditions and familiarity with the result of the medical examination of their patients and is therefore in direct answer to the needs and requirements of each case. The instruction is individual and personal as well as backed up by effective social service work.

### Causes of Phthisis Decline

The Department of Education also lends its broad support to the furthering of health measures for the protection and building up of school children. Some 120 open air classes are maintained for specially selected children from tuberculous families. The Division of Child Hygiene of the Department of Health in its regular inspections of school children uncovers a variety of physical defects which are brought to the attention of the parents and medical authorities.

New York City has been one of the first to extend attention to the so-called pre-tuberculous child. Preventorium, either in the country or on ferry boats used as day camps, have been developed and utilized.

Finally, the local tuberculosis associations have been especially active throughout these years in promoting the care of the tuberculous and in demonstrating the latest methods in this type of public health work. The Committee on the Prevention of Tuberculosis of the Charity Organization Society, and its successor, the New York Tuberculosis Association, the Brooklyn Tuberculosis Committee

and other local organizations have kept constantly on the alert to spread knowledge of the nature, care and prevention of tuberculosis. Public education and other methods of fighting the disease, traveling health exhibits, improvement in dispensary care of tuberculosis, the development of open air and nutrition classes for children, the rehabilitation of former sanatorium patients, the strengthening of auxiliary relief organizations have all been fostered and supported when necessary. Charitable and relief societies have been careful to give special attention to the demands created by tuberculosis; and the Home Hospital experiment of the Association for Improving the Condition of the Poor, the Altro Shop for workmen recovering from tuberculosis, of the Jewish Tuberculosis Committee, the Health Centers of the Red Cross and of the Brooklyn Bureau of Charities, and other developments have been notable products of these societies.

Passing from the consideration of the organization developed by New York against tuberculosis, we may now summarize more definitely the causes of the decline of this disease in the city. They can be condensed into the statement that all measures and agencies which have decreased the opportunities for massive infection and which make for the strengthening of human resistance or the maintenance of health have been effective in reducing tuberculosis; therein, in fact, lie the whole cause and preven-

tion of tuberculosis. More specifically speaking, the general causes of the decline of tuberculosis in New York City includes the following:

First, the general rise in the standard of living and the improvement of working conditions.

Second, the sanitary improvements

Sixth, the advent of prohibition, even if its observance is not absolute thus far must be recognized as playing a part in the reduction of tuberculosis, or the misery that led to it. Until recently, certain sections of the city were noted for their number of lodging houses which drunkenness

educational and health programs with increasing energy, until now they are demanding that malnutrition in children be wiped out and that all industrial workers have the benefit of annual medical examinations.

In New York City, tuberculosis is no longer the largest single cause of

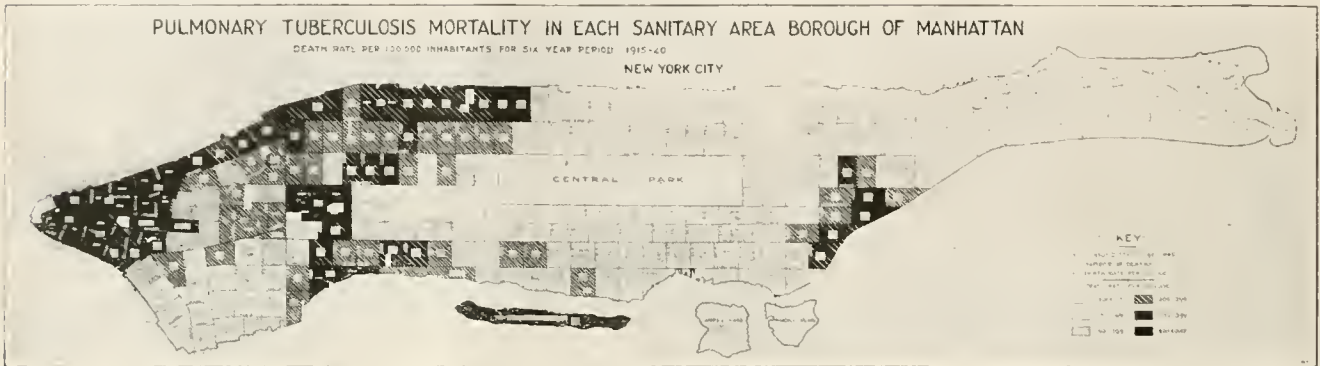

Diagram III.

throughout the city which exert a wide influence for the maintenance of health. Proper drainage, adequate disposal of sewage, and cleanliness of water supply are all most important in the improvement of health conditions.

Third, the tenement house law in New York City has brought air, if not sunlight, into every room where people live.

Fourth, it must be acknowledged that the coming into the city of a large group of people of Jewish stock, noted for their immunity to all diseases that are common to congested life, has injected a blood more resistant than that of other groups into the city's population and has materially lowered the local tuberculosis death rate. A recent study of tuberculosis mortality in the different sanitary areas of the city has revealed their very great influence in this direction. It was found that, in districts like Mt. Sinai, Corlears, Stuyvesant and the extreme lower East Side, which are largely Jewish, much lower rates prevailed than in similar sections where other nationalities reside.

Fifth, New York City has always retained a greater proportion of immigrants than other parts of the country. The application of the special immigration laws recently has practically prevented the incoming of racial groups from the Near East and poorer sections of Europe who always found it difficult to readjust their lives under the strange conditions of the new world, and who have contributed in the past a heavier mortality than the native stock.

kept filled with human derelicts headed straight for the hospitals. These lodging houses have lately been disappearing.

### Tuberculosis in the Future

The more specific anti-tuberculosis measures which have been developed in New York during the past few years and which, in addition to the general causes, have been accelerating the decline of tuberculosis, have included, as stated previously, legislation compelling registration of all pulmonary cases, anti-spitting laws, and pasteurization of milk. To these were added the supervision by the Department of Health of cases not under medical care, the requirement of a medical examination of all food-handlers before they could ply their trade, with consequent refusal to license those suffering from communicable diseases, and the constant segregation of advanced cases of tuberculosis in hospitals. The value of this last measure can be better appreciated when it is stated that at no time in all these years have there been fewer than 6,000 cases of tuberculosis in hospitals or in sanatoria out of town, with numbers rising as high as 9,000 in certain years. In relation to the total number of cases registered in the city which, during the past few years, has varied between thirty and thirty-five thousand, it may be said that in New York City there always has been at least 25 per cent of all known cases of tuberculosis under segregation.

Finally, the anti-tuberculosis associations have maintained their edu-

mortality. This deplorable eminence has been reached, instead, by heart diseases, though the unity of the cause under the latter group may well be questioned.

With the success already achieved in the fight against tuberculosis, it might be well to observe in what corners the disease is making its last stand. It is highest, first of all, in the Borough of Manhattan, and its greatest distribution is localized in the lower West Side, with island concentrations in the Bellevue middle East Side district and in some of the sanitary areas in the upper Harlem district. These strongholds of the White Plague are accounted for in certain racial groups, among whom a greater susceptibility should be recognized and more care devoted to their protection. People of Irish agricultural stock, the colored, young Italian girls, incoming immigrants, must all be recognized as being in more imminent danger of breaking down with tuberculosis under the conditions of city life, and special work among them should be undertaken. The present arrangement of clinic work on strictly district methods, with little regard to the character of the population, is after all, only a mass attack and should be followed by more intensive and special work in the sections just described where there is a higher incidence of tuberculosis. A study of the tuberculosis prevalence in different parts of the city as revealed by Diagram III should enable more direct and effective work.

Looking over the general population, work with certain age groups

should be emphasized. The greatest danger from tuberculosis is first among infants. At that time of life, when the body is not yet built up, resistance is low and infection frequently spells disaster. Not only the milk, but all dairy products used by children, should be pasteurized.

Among school children there is not quite the same danger since that period of life is noted for its freshness and soundness of organs and a more general enjoyment of health. However, there is a portion of them among the 25 to 30 per cent which many surveys have shown to be undernourished that will develop tuberculosis later. A few investigations in the latter group have further revealed that incipient or smouldering tuberculosis may be present in as many as one-third, it being the cause of malnutrition. Attention to this group will

therefore greatly reduce the toll of tuberculosis in later years.

At the time of puberty, a period of disturbance generally coincident with the leaving of home or school for the purpose of going to work, strain is added to weakness, and the first tuberculosis harvest after infancy is reaped. To these particular years of life, health organizations should give more attention, should demand medical examinations, correction of physical defects, and more rest taking than is required for other groups.

Among adults the greater danger from tuberculosis among workmen should receive separate attention. Thorough examination of all workers, men and women in shops, stores, or offices, should be instituted. Conditions should be ended under which such workers wait until advanced disease drives them too late to medical

institutions for care, as is now often the case.

The most significant part, therefore, of the tuberculosis program is that it opens wide the door for the maintenance of health in ways which its methods have shown to be successful. By not merely confining its efforts to the care of the tuberculous, but by recognizing that all things which make for the building up of resistance make for the maintenance of health, the tuberculosis program has opened possibilities which every health agency may well emulate and enlarge upon. The tuberculosis associations are fast becoming public health associations; the tuberculosis clinics are likewise becoming health centers. In the future their primary work will not be the care of the sick, but the assuring of health and productive enjoyment of life to all.

## The Role of Mental Hygiene in Education\*

Schools Will Advance Insofar as  
They Apply Mental Hygiene Rules

BY SIDNEY I. SCHWAB, M.D., WASHINGTON UNIVERSITY, ST. LOUIS, MO.

**A**T FIRST thought there seems to be no important connection between mental hygiene and education. A consideration of the question, however, will show that no educational attitude that ignores mental hygiene can be either good, useful, or socially respectable. Mental hygiene is one of the newest efforts to use the accumulated knowledge of the nervous system for the benefit of the community. What mental hygiene is, how the movement started, or, at least, how it received a new impetus scarcely twelve years ago is the best introduction to this lecture.

A book called "A Mind That Found Itself," by Clifford Beers, tells the story of a young man, a student of a great college, who entered on his university career with four ambitions, to secure election to a certain secret society; to become one of the editors of the college journal; to become business manager of this paper; and to get his degree: All these four things he did and in June, 1897, he graduated. For three years after leaving college he worked at various things, sometimes with success, and other times not. Always he was haunted by certain fears and he was forever

conscious of certain nervous symptoms which had burdened his life as a college student three or four years before. In 1900 he became mentally so ill that he had to give up his work and for the next three years this young man was sent to various hospitals, asylums, and private sanatoriums, a patient under treatment, guarded, deprived of his freedom, and under guardianship control. In this book he relates his experience, his symptoms, and all the curious and interesting phases of an acute mental illness. As he progressed with his illness through various institutions, treated by various methods, some intelligent and others very stupid, he became convinced that out of his own experience he had a message to deliver, and a thing to put over, and this was to acquaint as many as possible with the problem of the insane and to awaken in the minds of all who would listen an attitude of sympathy, of kindness, interest, and concern in the recognition, treatment, and above all, the prevention of insanity.

The book is an autobiography, a frank, sincere, and fair statement of a man's experience with his own disordered mind, and the social and institutional methods by which such a state of things is handled. Out of

this book came a very wonderful thing. Many read it and among the many were men and women whose souls were touched and whose vision was stimulated, and who determined that no longer, in this country at least, would the insane be without a national organization whose primary purpose was to see to it that as much knowledge as could be obtained about insanity would be properly spread among the people and that the care, treatment, and prevention of insanity would be made a subject of national scope. With funds furnished by this group, the National Committee for Mental Hygiene was started and the mental hygiene movement began, a movement which has penetrated many states and through which many state societies bearing this name have been founded. *The Journal of Mental Hygiene*, in the pages of which are reflected the story of the progress that is being made in the knowledge of insanity particularly from the social point of view, became the official organ of this Society. Clifford Beers is now secretary of the National Committee and his hard won experience in the difficult situation which confronts all minds that have gone astray has been turned to the advantage of all future or past victims of this disease. A significant quotation from

\*Delivered as a lecture in the second series of Washington University free public lectures on Medical Subjects and Public Health.

the pages of Mental Hygiene will serve to show the close connection which exists between mental hygiene and education.

It outlines the purpose of mental hygiene, which is to work for the *conservation of mental health*, to promote the study of mental disorders and mental defects in all their forms and relations, to obtain and disseminate reliable data concerning them, to help raise the standards of care and treatment.

### Responsibility of Education

From the very beginning, interest in the child began to influence the workers in mental hygiene for they saw that many cases of insanity could be traced back to occurrences and experiences in a child's life, and the influence of wrong ideas and defective environment. As soon as the mental hygiene movement leads back to the child and the adolescent, just so soon is its relation and intimate connection with education apparent. In a child's life the school stands out as the great formative mechanism of the mind and personality. A perfect education would so form and mold a child's growing nervous system that it would be successful in resisting the environmental conflict upon which a less elastic or trained nervous system would be completely or partially wrecked.

Leaving out of consideration the influence of destructive diseases on the brain, congenital malformation, and the effect of injury, it can be truthfully said that a large percentage of insanity might be prevented by proper mental training and discipline. How large this percentage may turn out to be is, of course, speculative but it is large enough for serious consideration. Not only does mental hygiene infiltrate the education question in this negative way, but it throws light on the normal human nervous system. When I speak of the nervous system I mean chiefly the mind which is nothing more or less than the "brain in action." There is a steadily accumulating lot of data which can be effectively used in the attempt to understand the intelligence of the child, its reactions, and the intricate series of reflexes, instincts and emotions of which it consists. The examination of these intelligences with the idea of finding out as much about them as possible in order to develop schemes of preventing improper use and subsequent bad results, is one of the most important tasks of mental hygiene.

For this reason education must be considered broadly from the standpoint that has come into fashion at the present time. Such a view is called biological because it attempts to see things through the history of the human race. If we think of education as the thing that enters into the life of each of us, some sort of definite realization of its importance can be obtained. It may be thought of, then, as a training or preparation which aims to fit an individual to meet successfully the contest with his environment. This thing he faces and must continue to face from his first moment of existence until he succumbs to that struggle by death. When this preparation is consciously prepared for and institutionalized, then there is an educational system or organization. Schools, colleges, universities have arisen out of the need, often dimly perceived, that such a preparation must be more efficient through some kind of organized effort.

A good deal of this thing called education is not and has not been recognized from the standpoint here laid down any more so than the urge towards a superior type, which results in the impulse called evolution, has ever been a purely conscious urge. It is obvious that with a notion of education implied in a definition such as this, a good deal of thought must be given to the planning of a proper method of imparting to the child such of this accumulated material as will make of him the best possible contender in the struggle of existence. Not only that, but as long as he lives he must, so to speak, keep himself fit and efficient as a part of a social organization whose purpose in a collective sense is successfully to triumph in the struggle.

In speaking of this struggle I am trying not to be dramatic, but rather do I want to suggest something in the nature of a biological effort. The term struggle in this sense rather connotes overcoming of difficulties. There are two kinds of struggles, one the individual, the other the collective or social, and in either or both, education in this sense is most important, and upon its proper use depends the success or failure, the ease or difficulty with which the final result is reached. The factors of this struggle are as manifold as the environmental conditions themselves. There are, however, certain facts open to any curious or inquiring mind, and it certainly is within the power of such a mind to attempt analysis of the multitude of

factors out of which this struggle grows.

Education being the instrument by which the struggle is made more fair to the individual, it is worthwhile to inquire into some of the ways by which a person may become educated and also to find out something about the things against which the struggle is directed and by what mechanism the person so engaged may be properly directed.

The infant or child must then be considered. The human factor is made up of what is called a mind, or intelligence, and a body, a very complex kind of mechanism which can transfer the content of that mind into various kinds of conduct. In addition, there are collected in this mechanism various impulses, tendencies, automatic acts which are called instincts, which create or modify conduct in ways only partially understood. For our purpose at present it makes no difference whether this machine we are considering is made up of a body and a mind of different origins or if the whole thing is one piece of intricate coordination. This, then, is the human machine for which various adaptations are essential in order to fit it to exist in an environment which is antagonistic to it.

### Must Use Intelligence

In educating the child, it is clear that the most important medium through which this effort is to be made is the intelligence; that is, the intelligence of the taught and the teacher. The latter is composed of the collective intelligence of the community and the holed down intelligence of those who have been engaged in teaching the previous generations of the human race. The record of that lies in printed books, the traditions, and all the documents that remain today in our possession. Upon the budding intellect of the child all this mass of experience must be directed as the formal aspect of education demands.

When the schools with their huge numbers of children to be educated loom up before us, then the real and tangible problem comes clearly into view. It is mass education that presents a test of any method, and it is this mass that gives to mental hygiene its opportunity. Few realize the problem, its complexity, and the enormous numbers concerned. It is well to start with some concrete notion of the task that mental hygiene has set for itself. In the State of New York there are attending public

schools about one million children; of this number forty-five thousand belong to the mentally deficient class. In the city of St. Louis there are about ninety thousand children in the schools. Of this number, if the percentage holds good, there are about thirty-six hundred mentally deficient. In the whole of the United States about thirteen million children attend the public schools today and of that number there must be roughly five hundred thousand deficient children. If the New York statistics, carefully collected by the Commission for Mental Defectives, apply to the whole of the United States about four per cent of all school children belong to this class.

### Provide Special Classes

The first task of mental hygiene, then, is to take these children out of the regular class rooms and to give them special training and care. Out of this mass of the mentally deficient there are a certain number that will automatically turn their defect into anti-social acts and behavior and finally come into definite conflict with the law. Another important aspect of the mentally deficient class is that they tend to become a drag upon the legitimate progress of the whole group with whom they are associated. Mental hygiene must step into the schools and separate this group, see to it that some kind of constructive effort is made for their proper education, training, and future care. At the beginning, it is not only selection but after care that must be thought of. Each child admitted to school should from time to time be examined by any of the numerous intelligence tests known now by various names which aim to compare the age level of a child with an intelligence level that has been determined by examinations in many normals. This gives a rough approximation of the intelligence level. When this level is far below the normal, the chances are that a lower intelligence is present. If from time to time such tests are made on the same child and no progress is found, then the defect is one that should exclude the child from normal classes. These tests are, of course, backed up by the observation of the teachers so that there are two kinds of judgment always present. If there is proper medical supervision of the school, each child that is found to be subnormal is examined carefully to determine if there is some factor apart from the nervous system that might be the cause of the mental backwardness.

Defects of sight and hearing and other defects are often found and their correction turns the child sliding down the pathway of mental deficiency into the pathway of the normal.

### Path of the Mentally Unfit

Let us follow a moment the fate of a child that is found to be mentally deficient if wholly unguarded by mental hygiene. After a while the child is turned loose from school, even after attendance at the special schools which almost every community is forced to have these days. The pathway from the moment of discharge frequently leads directly to the courts for infringement of law. These offences are at first trivial, then more or less important as idleness, laziness, and criminal opportunity present themselves. From the courts, even if they be juvenile ones, the way towards homes and reformatories is so direct that it is a wonder that any escape. From this station to the prison and death house in many instances there are not many milestones in years.

If the problem of the mentally deficient is approached from the point of view of mental hygiene, the fate of the child is quite different. Such children find their way into special clinics where trained experts in nervous diseases, psychologists, and social workers are at work. These are concerned in the problem of the mentally deficient as a primary thing. Their outlook is sufficiently social to see in this discarded material a potential value that under proper guidance and under expert direction may be trained to useful lives and may reach levels of contentment that may block the anti-social nature of many of their impulses. In such clinics, the children are separated into various groups, each one of which may be directed towards a definite purpose. The more advanced are sent to special classes the chief function of which is training for future employment at that grade of intelligence level that is fitted to the special intelligence at hand. Groups are directed to wage earning colonies or selected homes, all of them with the goal of employment in mind. The whole effort is imbued with the spirit of positive achievement as contrasted to the negative fate of prison, idleness, prostitution, and illegitimacy.

No state in the Union has begun to approach the solution of the mental defective in the way that has been here outlined. No state has been courageous enough to face the tremendous outlay in money, effort, and

personnel. In the State of New York, which is doing the most, 70 per cent of the defectives are under no supervision whatsoever; that is, thirty-two thousand of the forty-five thousand are without any care, direction, or supervision at all. Translate into your own state or city some of these percentages and gather in your imagination the burden of crime, destitution, immorality, and illegitimacy. In this way you may see what society is paying for a system that discards, except in a small percentage of instances, the collected experience which mental hygiene has made available for use.

I have tried to show how mental hygiene must infiltrate into these earliest years of the school and how it must see to it that the mentally unfit, even if temporarily in that condition, should be segregated for special training and care in order that this large number of boys and girls can reach a certain level of achievement and can be made to be of use thus diminishing if not completely preventing the chances of criminal careers. This may be termed, as far as education is concerned, a kind of negative aspect. It is far more interesting perhaps to look into the activities of this same movement when it functions in a more positive way and when it attempts to examine into the methods of teaching through the intelligence of the child and through that of the teacher by what may be termed mental discipline, using this phrase in its old usage.

In the sense that I am using the term mental hygiene, it should suggest that it makes use of all the knowledge at our disposal of the nervous system in all of its manifold activities and that it is especially concerned with the utilization of such physiological facts that have been obtained from the study of the individual in and out of the laboratory and the wards of a hospital. No one, as far as I know, has made an effort to collect these experiences so that they may be easily available to the educator or the teacher. It will be possible therefore to touch only on the more significant phases of this very broad subject.

When a school system is examined, that is, a system of teaching that is applicable to large numbers of children, such as would be represented by the total attendance of one of the grade schools, one of the things that stands out is the tendency to regard all of the children as having the same mental abilities, identical tastes, and identical natural endowments. A

plan of instruction is put through, therefore, to meet the average mental needs of such a group and an assigned task or sets of tasks are measured out. The rate of progress is the rate of progress for the whole group which is of course that of the minimal ability of that particular group. What has the physiology of the nervous system to say to this and what has it to suggest as a remedy?

The answer is clear. It would point to the fact that the most important single factor in the development of the human race is that of differentiation of types and that differences are more significant than likenesses. Progress consists in the proper utilization of differences and a competition in the items of dissimilarity, so that the more useful, valuable, and on the whole beneficial tend to survive.

The answer of mental hygiene would be very much the same. Whatever might be said about innate intelligence or the primitive native endowments of the mind, there is no question about differences when the school age is reached. Here, there is no uniformity of mental receptivity and certainly none concerning the impulse, the liking, and the ability to learn. There must be in any scheme of instruction sufficient elasticity to meet the varying requirements of the individuals forming a group to be taught.

Another thing that should be pointed out is that the principle of selection that is suggested is supported by accumulated experience in dealing with many minds that come into the province of the activity of a mental hygiene movement. There is nothing new in this view, of course, and there is no lack of proof that educators have long ago seen this, and that all kinds of efforts have been set into activity to provide some kind of arrangement through which the quality of difference might be made use of to the advantage of the whole group. The fixed curriculum as contrasted to the elastic scheme is one that appeals to the physiologist and to those that see in the school system the greatest hope that exists today for the mental training of the future citizen in the complex life of a democracy. Mental hygiene has its attention focused on the two groups that stand out in any fixed method of training. The backward and the advanced group each contain the elements of future harm and of future good.

The proper attitude to each of these is a province that mental hygiene

might well enter, and by entrance I mean through advice, suggestion, and also by pointing out the dangers in the too rapid progress that might be made by the selected group and the risks to the backward group either by over-exertion or through a growing disinclination to attempt to reach the average level. The solution of this difficult problem would seem to lie in some attempt to distribute the task in such a way that from the outset selection be made according to prospective ability, so that each group might measure up to its full capacity at acquisition and thus fully realize its natural and acquired endowment. All this would imply a careful consideration of individual ability and some approach at measurement of potential intelligence.

A natural question here would be in regard to the means by which this might be accomplished. With the great number of pupils and the small number of teachers how could anything like such a task be put upon them? Under present conditions, it is impossible, but a point of view might easily be brought about through which the teacher becomes increasingly aware of the very real danger to the mental health of the children in applying a too rigid system of instruction. By steadily emphasizing notions of this kind and suggesting that education is the proper training of children for their future contact with the realities of life, a point of view might be finally reached that would insist that even in matters as professional and technical as planning a curriculum there might be a place for the consideration of the factor of mental hygiene.

It is more interesting and certainly less technical to get away from the method of teaching and the stuff to be taught and pay some attention to the object of this activity, that is, the child and some of the problems from the standpoint of the make up of a child which are worth considering. It is well to realize that a good deal of the popular notions about the psychology of the child is based upon misconceptions and rather strange notions derived from a mass of poorly digested observations. A good deal of this misconception, I believe, is due to the view that the brain of an infant represents a mass of innate organized power that is inherited from the parents or from the race to which he belongs or from the stock out of which he has sprung. As a matter of fact, the brain of the infant, certainly in the early months of his ex-

istence and up to the time that he can receive notions from the outside world and can give some out himself, is made up of purely instinctive impulses which mainly have to do with primitive needs.

The innate power, that thing that differentiates one brain from another and which causes the tendency to differ to which I have previously referred, lies very likely in certain very material endowments that are quite like the superior power muscularly that one child shows over another. That is, there is laid down, so to speak, in each brain a certain individuality of cell activity, a certain quickness of reaction, a certain capacity to respond to stimuli, and so on. It is out of these and many others that are not known that the future qualities of mental acquisition and the utilization of the things so acquired arise. The future scientist is not born with a brain that is destined to be capable of scientific reasoning any more than the future artist or republican is born with something inherent in his mental make up that will drive him to these callings or that state of mind. The point is that there is a general lot of capacities that all brains might be supposed to possess; that is, such brains that are not injured or the subject of early diseases or definite abnormal inheritance in the way of syphilis or other conditions of that sort. This means that in the early years of a child's life he responds as far as his mental life is concerned to certain habits and is in reality up to the fourth or fifth year largely a mechanism of habits and its handmaid imitation. The instincts with which he comes into the world are capable of being trained into purposive and useful and profitable types of action or conduct, and it depends very much upon the early direction given to them whether they turn out to be advantageous things for both the individual and society or not.

The child enters the region of formal education just as his instinctive life is passing out of the pure habit stage into that in which the responses from the outside world begin to develop in him powers of selection, choice, and discrimination. It is also well to note that the school represents to such a child his first contact with society; that is, social existence outside the restricted limits of home. The habit stage is never, of course, completely done away with, but new habits both bad and good are a little more difficult to acquire with the

passing of the first decennium of a child's life. I mean here habits that are entirely new; and I refer here to mental habits, or possibly I can better express this by saying habits of thinking.

In the years now under consideration there is great power for acquiring things, especially such as are carried in by sound and sight. Memory, retentiveness, attention, concentration, and a host of most valuable items in the process of thinking are acquired and through training, discipline, imitation and inhibition the machinery of thinking is slowly laid down. The instinctive impulses and the purposeless and often destructive tendencies associated with them are arranged in some kind of orderly fashion, so that when the first phase of adolescence is reached and the period of early conflict begins, the child may have ready at hand some means by which this period may be safely passed. The age of conflict, the awakening of self consciousness, and the capacity to see a bit into the problems and not merely to beware of them may be fixed roughly at the period of high school.

I have sketched the various ages of the child merely to be able to point out some of the uses that mental hygiene may be put to, if education is looked at not merely as a process of imparting what is called knowledge to the prospective adult, but as a training and preparation for contacts with the world as it exists, a hard, difficult place to live in, full of destructive things and one where an individual who relies on impulses will find difficulty in adjusting himself.

An important thing for mental hygiene to do is to guide the proper use of effort made by the mind in acquiring the necessary items of an education,—I mean by that how far it is wise to go in overcoming the natural resistance which is almost always present in the mind of the average child when it comes to the performance of definite intellectual tasks. A way must be found somewhere between the actual forcing and the natural impulse, the instinct to learn through which the child in or out of school is impelled on his way to some sort of final mental achievement in whatever form that may eventually take. This brings in naturally the place which discipline should occupy in any system of teaching. There has been a good deal said on this subject lately and much criticism has been directed to the present methods of development and enforcing it.

What is discipline and what pur-

pose does it serve? It can be compared to something that is present in almost all of the things that are done in the physiology of the body. There is no mechanism that prevents a too excessive use either in rate or power. This is seen in the regulation of the beat of the heart and in the limitation on certain of the reflexes. This principle is called inhibition. It is, on the whole, one of the most valuable and necessary of the automatic controls. A certain analogue of this function is found in the mind. Here it is called repression; that is, the power to prevent certain ideas on their expression from becoming articulate or transformed into types of conduct. Discipline makes use of a similar mechanism when it aims to prevent certain acts or impulses from being translated into kinds of conduct that in the long run are disadvantageous to the individual and his social environment. Often the power that makes discipline effectual must come from the outside, and, indeed, in the beginning and as an educational force, it must come in that way because there is nothing in the mind of the child, as such, that has any such inherent power. The effect of school discipline, if wisely enforced, creates a tendency towards a broader understanding of conduct and removes from the mind of the child one of his most dangerous tendencies; that is,—to regard each thing that he does as affecting in its consequences himself alone.

### Rôle of Vocational Guidance

There is little doubt that discipline in conduct is the first step to the acquisition of the more valuable trait of mental discipline. This is one of the important features in the successful performance of any kind of task and is necessary in the large activities of any kind of communal life. So valuable an item in the training of a child must contain many mental aspects, and to the mental hygienist the proper use of discipline is of the greatest interest. Some one has pointed out the fact that the first thing to teach a child is to talk and the next thing is to teach him not to talk. This is the nub of the matter and contains the gist of discipline.

Whatever aspect of education is regarded as of importance, certainly that point of view which stresses the training of a child for his future contact with the world touches all of us and takes hold of us with a definite feeling of conviction. What is the child being trained for and what is he to do with the training he has ob-

tained after he gets it? Does education presuppose a selective tendency towards future activity, and does or can its training be aimed at some sort of future activity, business calling, or profession?

Vocational guidance should be a part of education. It is here perhaps more than in any other phase of the educational system that accomplishment is so far behind ideas, hopes, and dreams. Throughout the school life of a child there looms up the future and the future means chiefly a business in life and a selection of the sort of business it shall be. The great majority of the graduates of the secondary or high schools go out into life and take up this or that calling without the least sort of preparation for it. By chance or by force of circumstances a place is found and that place bears no relation at all to the special type of mind or personality the individual may have. To the mental hygienist this sort of crude chance is full of danger and in it he sees all kinds of harmful possibilities.

Many a case of mental breakdown is due to the wrong selection of a trade or business and many an individual sacrifices the best that is in him by steadily plugging along in the wrong game until he becomes after awhile the tired routinist, a very common type of our citizenship. Something to lighten this burden might be done by allowing the mental hygiene point of view to play its small part in the educational system, chiefly through an attempt at early selection and a constant study of the capacities, tastes, and interests of the child as he proceeds on his way through the stages of his education.

In the records kept of pupils in the secondary schools how often is there noted any significant data in regard to what they would seem to be best fitted for, how far a special training would be advised, and how far it ought to go? Certainly a start in this direction might be made, if only to give to education an aspect of practical application which it sometimes appears to lack. Much of this would indeed be experimental in the start and there would be considerable guess work and mistakes would be made, but it might prevent in some instances, where free choice is possible placing, the youth or girl in the kind of work he or she is obviously unfitted for. I am trying to keep in mind, of course, the difficulty of getting jobs in any case and the necessity often present to take what there is, but I am sure

that there will come a time when there will be some other factor in choosing a trade except that of dire need and immediate necessity.

Before closing I want to quote a few sentences from a distinguished neurologist who has written wisely and entertainingly on education. The essentials of education Stewart Patton says are (1) knowledge of actual life; (2) definite impelling interest in some phase of life; (3) information gained from actual experience of a person's own adjusting capacity and limitations; (4) the cultivation of the emotional attitudes and habits required for recognizing and facing reality. People who have acquired these things are insured against nervous breakdowns, do not occupy posi-

tions they are not qualified to fill, are not intoxicated by intemperate idealism, do not develop a psychology of life based upon personal grouches or make the fatal mistake of persuading themselves that their own pronounced defense reactions against reality are virtues. It is my own firm conviction that a properly educated community would be one in which the percentage of insanity and nervous disease would be very small. Education in this sense is possibly the most important means of prevention, ready at hand against the burden of nervous and mental diseases that so frightfully weigh down the community of today. Mental hygiene in its relation to education furnishes the channel through which the necessary information and

experience might permeate the educational system and reach the desired end. Education then might well be regarded as the most important of our social businesses. It is the most vital element in the problem which life presents and without it life is an almost impossible task to get through with. It is a matter in which the wisest and most thoughtful minds of a community should be concerned. It is one of the institutions in the life of a democracy which should have no political tinge and no political aspect. It is a thing so necessary, so vital, and so much a part in the lives of each one of us, that no selfish, inexpert, narrow, dull or partisan individual should be permitted even to touch it.

## Birmingham Provides Pools for Its Workers

THAT cities and industries are realizing the workers' need for wholesome recreation is again evidenced by the combined undertaking of the city of Birmingham, Ala., and the Tennessee Iron and Coal Company in completing last summer two swimming pools. These, located within the city limits, are within convenient walking distance of the industrial section. Of the total cost of erection \$45,000, the company furnished \$25,000, the city paying the remainder. The pools measure 50x100 feet each and are 3½ feet deep at the shallow end and 9 feet deep at the other. They are separated by a 12-foot concrete walk.

Helen Bethea describes the city-in-

dustry owned pools in the April *American City* thus:

The pools are not covered but buildings practically surround them. At one end is the filtration plant and at the other the gallery for spectators. On both sides are the bath-houses, administration building, and lockers. Access to the pools can be had only through doors and passages.

Each pool which has a capacity of approximately 250,000 gallons, is filled with filtered water from the city supply which is pumped from the lowest point in each pool by a centrifugal pump and forced through pressure filters and thence to the ultra violet ray sterilizers from which it is returned to the pool. The piping is so arranged that the water is returned to the pool through four orifices located at the shallow end of each pool near the floor. By this means almost perfect

circulation is maintained as is demonstrated by the fact that bathing caps, belts, and other articles lost in any part of the pool always drift rapidly to the grating over the suction pipe to the pump.

To insure a fresh supply, the water in both pools is turned over every twenty-four hours, and although the attendance is from 300 to 2,000 a day, bacteriological tests have shown the water to be satisfactory at all times. The pools are emptied and scrubbed each week to destroy the algae which grow along the sides because of the uncovered condition making the water appear dark. After the scrubbing, the pools are sprinkled with chlorid of lime. The addition of bluestone will retard the growth of moss.

Two pools were built last summer and financed jointly by the city of Birmingham, Ala., and the Tennessee Iron and Coal Company. The pools measure 50x100 feet and have a capacity of 250,000 gallons each. The water is pumped through pressure filters and thence to ultra violet ray sterilizers, thus assuring a fresh, pure water supply at all times.

# The Veterans' Mountain Camp

BY CHARLES POPE CALDWELL, CHAIRMAN, VETERANS' MOUNTAIN CAMP COMMITTEE, NEW YORK CITY.

**T**HE Veterans' Mountain Camp, located on Big Tupper Lake, New York, has been established by the New York Department of the American Legion as a convalescent camp for discharged veterans to supplement the hospitalization facilities of Government and private institutions.

In the beginning preference will be given to legionnaires from the state of New York, but as the Camp develops and its facilities become larger patients will be received from other states. There is no free convalescent home that we know of. The Government is not expected to give hospitalization to the veteran who cannot

ican Legion in the Department of New York will be a member of the Corporation. The Board of Directors consists of forty-five men, including the Executive Committee, American Legion, Department of New York.

Twelve hundred and seventy-five acres of land have been purchased on the south end of Big Tupper Lake, surrounded on three sides by twelve thousand acres of State Forest Preserve. The altitude is from sixteen hundred to twenty-three hundred feet. On the property already are twenty or more buildings, one of which is being used as an infirmary and the others for purposes essential to the Camp. A number of open log lean-to's for

recreation hall with bowling alleys, tennis court, water works and all the accessories of a millionaire's beautiful home in the mountains.

We are now raising our endowment fund in order that the Camp may be maintained and operated for all time. It will belong to the veterans of the Armed Forces of the United States, the endowment will be theirs, the income theirs. While it will be under control and for the benefit of those who need the care such as the Camp can give, no one who is a denizen of the camp will feel that he is accepting charity, any more than a son would feel in accepting a check from the Trust Company, acting under a Trust

One of the twenty buildings already on the grounds of the Veterans' Mountain Camp which is used as a bowling alley and recreation hall.

trace his disability to injuries in line of duty. No such limitation will be imposed in the Veterans' Camp, however, and tuberculosis developed after the time specified in the Sweet Bill will be treated by us free. The Legion feels that all who have borne or may bear arms in the defense of the country are entitled to aid, comfort, and support when in distress, and we propose to treat all alike, rich or poor, young or old, male or female.

The Camp has been incorporated under the laws of the State of New York and every member of the Amer-

ican Legion in the Department of New York will be a member of the Corporation. The Board of Directors consists of forty-five men, including the Executive Committee, American Legion, Department of New York.

Twelve hundred and seventy-five acres of land have been purchased on the south end of Big Tupper Lake, surrounded on three sides by twelve thousand acres of State Forest Preserve. The altitude is from sixteen hundred to twenty-three hundred feet. On the property already are twenty or more buildings, one of which is being used as an infirmary and the others for purposes essential to the Camp. A number of open log lean-to's for

Fund created by his deceased father.

Operation of the Camp was begun on a one hundred bed basis. As the average stay of the convalescent is about three weeks, we expect, therefore, to take care of approximately seventeen hundred the first year. In time we intend our Camp to develop into a sanitarium and then into an old veterans' home. It will be open to men and women. An honorable discharge from the Armed Forces of the United States, showing service in time of war and need for the care and treatment such as we can give

will be a ticket of admission. Transportation to and from the Camp, food, clothing, lodging, medical care and treatment, together with such recreation and entertainment as will be advisable will all be free. A millionaire may come to the Camp, but he cannot pay for its service. He may donate, but he cannot buy. All will be treated alike.

There are no overhead charges, no salaried officials, and no charge for office space. Our expenses, including appraisal, inspection, examination of

title, etc., have been considerably less than 10 per cent of actual cash received, and the bargains struck in the purchase of property have been so advantageous that we can safely say that for each one dollar contributed to the Veterans Mountain Camp one hundred cents goes to the sick man.

A medical staff is in process of organization and we hope to have the largest and most efficient medical supervision of any hospital in the country.

## Block Traffic to Give Children Play Space

Underwood & Underwood.

In an effort to give tenement children a safe place to play, Mayor Hylan has ordered certain New York City streets closed during the summer months. The Merry-go-Round is a popular amusement on these play-streets and on hot days the fireman's hose furnishes cold showers to the hundreds of swarming children.

## Swimming Pool Tests

WHEN it is realized that communicable diseases, particularly infections of the eye, ear, nose, and throat, are easily spread in swimming pools, the necessity for adequate sanitary tests becomes apparent. That the usual methods are not sufficient to check such contagion is the belief of J. W. Robinson, M.D., Deputy Health Officer, Los Angeles County, California who in the *California State Journal of Medicine* sets forth an efficient disease-preventing program.

"The usual methods of testing water fail to show the danger caused by mucous or pus which are separated from the swimmer by direct washing, coughing, sneezing, or expectorating,

and this leads to false security," states Dr. Robinson. "Many of the colds caught are actually swimming pool infections."

The rules of the California State Board of Health have recognized the dangers of such infection and Rule 3 states that facilities for adequately protecting the pool waters against unnecessary sputum contamination by bathers must be provided. For this purpose convenient and proper places for expectoration should be provided as well as means for frequently or continuously skimming off the surface water. A combined overflow and expectoration gutter is usually the best method of handling the difficulty. Rule 4 states that all persons known

or suspected of being afflicted with infectious diseases shall be excluded from the pool.

While these rules are considered by Dr. Robinson as steps in the right direction, nevertheless he feels they are not specific enough and makes the following recommendations:

(1) In order to prevent stagnation of waters in corners except what is overcome by the movement of bathers, the location of supply and drainage pipes should be specifically stated by boards of health or of engineering.

(2) In addition to rules concerning clearness and bacterial counts, there should be a rule stating the frequency with which water should be changed on a basis of a certain number of cubic feet to each bather or in ratio of the surface area for each bather. There should be a constant flow of water from the surface into the overflow gutters, and this water should be supplied by as many intake pipes and removed by as many overflow pipes as is necessary to keep all parts of the surface of the water changed. To accomplish this satisfactorily, the flow of water should be across and not lengthwise of the pool in order that mucous floating on the surface would be there the minimum amount of time.

(3) Methods should be worked out of skimming the surface of the water to examine for pus or other infectious material.

(4) A law should be enacted making it a misdemeanor for an infected person to enter a swimming pool.

## Unique Recreation Plan

A City Recreation Committee has been formed in New York City to work toward the adoption of a comprehensive recreation plan for the city and has drawn up a definite set of immediate tasks which are published in *Better Times*. The following committees have been appointed: Recreation budget, Raymond Ingersoll, chairman; construction of new school buildings, Clarence A. Perry, chairman; community recreation programs, Charles C. Bauer, chairman; public bathing facilities, Mrs. Mary G. Simkhovitch, chairman; summer camps and bathing beaches, Mrs. Sidney C. Borg, chairman; commercial recreation, Mrs. Henry Moskowitz, chairman. Mrs. Frank A. Vanderlip has been elected chairman of the City Recreation Committee.

The fourth annual meeting of the Montana Public Health Association was held at Great Falls, July 10 and 11, 1922.

## Biological Tests in Nutrition

NOT very great success and very little precise understanding with regard to dietary deficiencies were achieved in the early investigations of rationing on the basis of energy requirements. As chemistry progressed and became able to reveal some of the secret processes of metabolism newer conceptions of the adequacy of diets, the underlying causes of deficiencies, were worked out by checking the findings of the laboratory against biological experiment. A century of patient labor has gone into the work of analyzing foodstuffs, searching out the number and character of the processes of metabolism, and observing the effects of simplified diets by animal experimentation.

It was long after nutritional experiment was concerned with working out adequate diets before the students of nutrition discovered the parallel between public health conditions and the dietaries of the people. Man has been ingenious enough to work out for himself sufficiently varied diets to maintain under ordinary conditions the necessary balance. Conditions like scurvy, neuritis, pellagra, and other deficiency diseases were in times of famine or in post-war periods ascribed to general stress rather than to dietary errors.

The newer nutritional conceptions are far reaching in significance. People generally are beginning to appreciate that the chemical analysis of foods supplies for protein, carbohydrate, fat, and mineral salts does not reveal their biological properties, but that the nutritive requirements of the body include the vitamins A, B, and C, and the more recently announced Vitamine D discovered by McCollum in his studies of the disturbed metabolism of calcium and phosphorus in rickets.

The vitamin concept, however, should not cloud the issue of a perfect food supply. There are many grades of malnutrition between the condition of well being on the one hand and deficiency diseases on the other, and there is the need of popularizing the newer knowledge of nutrition. McCollum, particularly, is insistent upon the newer classification on the basis of biological properties as foods. Those "which are faulty in certain respects are classed together, irrespective of their chemical composition. Thus the bean with 23 per cent of protein is logically classified with the

potato which has but 2 per cent because bean proteins are of very poor quality and are of little use for the promotion of growth or for the repair of tissue waste," this classification being the outcome of the discovery that all vegetables foods which have the function of storage organs (seeds, tubers, fleshy roots) have similar dietary properties and similar deficiencies regardless of their chemical composition as revealed by the standard food analysis. The highly specialized muscle tissue falls into the same class with the cereals in respect to its dietary properties and differs very markedly from the glandular organs just as do the seeds, tubers, and fleshy roots from the vegetative parts of the plants—the leaves. Milk and the thin leaves of plants are of spe-

cial value for enhancing the dietary properties of nearly all other foods, and they are therefore of particular interest and importance. McCollum for this reason terms them "protective foods." In a lesser degree, eggs and the glandular organs of animals serve this purpose of improving the quality of cereals, tubers, fruits, roots, and of meats of the muscle type.

McCollum holds that the science of nutrition is of the greatest value in preventive medicine. However, he advises particularly against food fads. The unfortunate individual who through faulty habits of living, finds at an age at which he should still be in possession of the full vigor of middle life, that his efficiency is diminishing and the joy of life slipping away will, he says, gain much more through adhering to a diet well balanced than through clutching to this or that dietary whim or fad.

## The Engineer's Standpoint

INFLUENZA from the viewpoint of the physician has been a common topic for articles in medical journals for the past few years. The subject is now being taken up by engineering journals, and in the April and May issues of *Municipal and County Engineering* Dr. William Paul Gerhard, C.E., Consulting Engineer, traces the history of the disease and the police and sanitary regulations helpful in preventing it.

Influenza is not a new or mysterious disease, but, according to Dr. A. Ripperger of Munich, was first known in 1387. It reoccurred in epidemics four times in the fourteenth century, twice in the fifteenth, four times in the sixteenth, six times in the seventeenth, and seven times in the eighteenth century. The disease in Italy was called "influenza" owing to the belief that certain evil currents flowed from the stars to the earth. In France it was termed "La Grippe," and Germany "Russian catarrh."

The astounding spread of the disease is shown by statistics of new cases in New York City in 1918. Beginning with 127 cases in the week ending September 22 and no cases of pneumonia, the number jumped by thousands each week till in the week ending October 27, 1918 there were 26,166 cases of influenza and 12,369 cases of pneumonia, with 2,497 deaths of the former in the same week and 6,032 deaths from the latter.

Although the disease is an old one

and well known to the medical profession its control has not always been successful. The fact that the period of incubation is shorter than in other infectious diseases, that the disease is infectious before the true nature of the illness is diagnosed, and that patients with mild cases continue to walk about has made the disease difficult to control.

That the municipality can by police and sanitary regulations do much to offset the spread of influenza is the belief of Dr. Gerhard. Some of the regulations considered valuable are the anti-spitting ordinance; placards regarding the use of handkerchief; use of suitable substitutes for handkerchief; prohibition of common drinking cups and roller towels; no permission granted to visitors to sick in hospitals; placarding of houses; no public funerals; avoidance of handshaking; limiting hours of work; staggering hours of work to avoid congestion of traffic; cleaning and disinfecting public conveyances; limiting size of public gatherings; closing of schools in some communities.

Sprinkling of streets with a disinfecting solution to lay the dust should be another sanitary precaution of a municipality during an epidemic.

Street gutters and catch basins at street intersections should be carefully examined at frequent intervals, swept, flushed and kept scrupulously clean by the force of the city engineering department.

# Digest of Sanitary and Hygienic Advance

THE health officer will find in this department each month a more or less technical report of the newer methods and significant trends in the public health field.

## Prevention of Simple Goiter

Kimball (*Am. Jr. Med. Sc., May-22, C LXIII, 5, p. 634 et seq.*) after a careful review of the history and world distribution of simple goiter, i.e., thyroid hypertrophy, concludes that this condition is to a large degree preventable. This is an opinion which should receive careful consideration by all hygienists. His data on the incidence of goiter in the United States indicate that this disease is widespread and in certain areas, like the Great Lakes basin, is endemic and constitutes a public health problem of considerable magnitude. On the supposition that goiter is a deficiency disease which may be prevented by the administration of iodine, in April, 1917, he examined 3,872 girl pupils in the public schools of Akron, Ohio, with the following results:

Normal thyroids	1,688	43.6%
Slightly enlarged thyroids	1,931	49.9%
Moderately enlarged thyroids	246	6.3%
Markedly enlarged thyroids	7	0.2%

Of this group one thousand girls voluntarily took the prophylactic treatment of sodium iodid. In November, 1917, 4,415 girls were examined of whom 2,643 were in the group examined in the preceding April. Of these 764 had taken the prophylactic. There was no increase in the normal thyroids of any child who had taken iodine, indeed one-third of the small goiters had disappeared and one-third of the moderately enlarged thyroids had decreased in size by 2 cm. or more. After considering these and many other data, Kimball concludes that iodine is an efficient prophylactic against simple goiter. While any method which will increase iodine absorption may be used, e.g., by leaving an unstoppered bottle of tincture of iodine in the schoolroom, he believes that 2 grams of sodium iodid administered twice yearly is a harmless and efficient means of prophylaxis.

The occurrence of familial tuberculosis is in the inverse ratio to the family income.

## The Schick Reaction

Vincent, Pilov, and Zoeller before the March 11, 1922 meeting of the Biological Society (*Par. Med. XII, No. 12, Mar. 25, 1922, p. 260*) reported that they had stated to the Congress of Strasburg (1921) the first results given by the intradermic reaction to diphthero-toxin upon 2,816 men during an epidemic of diphtheria. Strong or faint, the positive reaction implies a receptivity for the bacillus of diphtheria. But this receptivity differs according to the intensity of the reaction; thus out of 728 men having a strong reaction there were twenty-four cases of diphtheria or 32.9 per thousand while out of 616 with faint reactions there were 12 or 19.4 per thousand and out of 1,472 having a negative reaction, four or 2.71 per thousand had diphtheria and of mild benign type only.

## Trichuriasis

Spruit, (*Am. Jr. of Trop. Med., 1, 6, p. 375 et seq.*) points out the interesting fact that *Trichuris trichiura* is not, as has been commonly supposed, a harmless inhabitant of the cecum but may produce serious symptoms, or even death. In support of this, he describes the pathological changes found at necropsy. He also notes the extreme pessimism of medical literature regarding the specific treatment of this condition and reports the failure of *Chenopodium* to remove the parasite. These facts are very important, since everyone who examines stools in the tropics is struck by the almost never failing presence of the *Trichocephalus* therein. In Colombia and Brazil, the fresh juice of the white fig tree (*Ficus glaberrima*, *F. latex*, *F. laurifolia*) is quite generally used as a vermifuge and is considered as a specific for trichocephaliasis. Spruit used the juice or sap, which is known in Colombia as "Leche de higueron," both fresh and preserved in chloroform. It is obtained from slashes in the bark of the tree or by cutting off a branch and collecting the juice ("lech") which flows abundantly. According to Montoya (*Rep. de Med. y Cirg. XI, 8, p. 432 et seq.*) this is a yellowish-white, syrupy liquid resembling cow's milk. When fresh, it is an acid emulsion of rubber and resins, albumin and an ammoniacal substance fermenting easily with the

evolution of carbon dioxide and an increase in acidity. Montoya believes that the active agent (as yet not isolated) exists in this ammoniacal substance and outlines a table of dosage varying from 15 grams at one year of age to 45 grams for adults. Spruit puts the patient on liquid diet the day preceding the treatment; at 8 p. m., 30 c.c. cream of tartar in a glass of sweetened water is administered; at 6 a. m. and 8 a. m. the following day, 16 c.c. of fresh *leche de higueron* in half a glass of cow's milk; at 10 a. m., 60 c.c. castor oil. With the chloroformed juice, the dose was increased from 16 c.c. to 20 or 30 c.c. and magnesium sulphate was used instead of castor oil. Montoya follows practically the same routine but gives the *leche* in a single dose. He believes that ordinarily *leche de higueron* is non-toxic but reports that there are occasionally alarming symptoms such as cramps, delirium, sudden urticaria, syncope, vertigo, convulsions, rectal and vesical tenesmus, partial suppression of urine, etc., which disappear completely in a few hours. Spruit reports that in his series of cases there were usually no subjective symptoms when the pure juice was used, occasionally burning in the rectum and around the anus was complained of but ceased in a few hours. *Ficus latex* is widely distributed in the tropics and the use of its juice for the expulsion of *Trichuris* seems to be a practical and easy method of treatment.

## Certify the Stillborn

The Chinese ante-date the age of a child nine months, a logical decision in more ways than one. When we consider that 47 per cent of the deaths in the first year of life, as reckoned by our Occidental methods, occur within two weeks after birth, it would appear that much good might be attained by adopting the Chinese method of age calculation, since under that system, we would be more apt to direct our attention to the untoward eventualities of intra-uterine life. It probably would be difficult to get Americans to thinking of a child which dies seven days after delivery as being 287 days old but it certainly would wake people up to the tremendous waste of young lives which is now going on. Another aid to this end would be the abolition of the term stillborn and

the attendant negligence which its use begets. As at present used, still-born is a blanket-term which hides much carelessness and cloaks much ignorance. Its abolition and the requirement of a death certificate for every human death will disclose to us much maternal toxemia and specific disease, as well as many deformities and traumas of which we now have little accurate knowledge. Surely a child which is born alive and then dies is no deader than one which dies before separating from its mother, and surely, if we are going seriously about the business of conserving human life, the knowledge of the cause of death is equally important in both cases. The Church and the Law have long recognized a child conceived as a living entity and the profession of sanitary medicine should take the same stand. Society should demand that earnest inquiry be made into the mechanism by which any child is killed and a properly executed death certificate is the beginning of the search for this information. Doubtless it would result in a tremendous increase in the death-roll which is now laid at the feet of syphilis, but so much the better, since it would demonstrate the necessity for ceaselessly combatting this arch enemy of the human race.

Regular, periodic, physical examinations at present constitute the most immediately available weapon against heart disease.

### For Rodent Destruction

Mix thoroughly one pound of barium carbonate with three pounds of flour in a clean enameled basin. Stir in enough water to make a fairly firm paste. This will make 2,300 baits of three grains each of barium carbonate. It is necessary to make fresh baits daily since hard stale bait is rarely taken by rats. The baits should be distributed in groups of four in situations which are frequented by rats. A careful record should be kept of the number and location of the baits distributed and a note made of the number taken. The poisoning of rats is greatly facilitated by rendering food stuffs of all sorts inaccessible to them.

### Alastrim

The December number of *Sanidad y Beneficencia*, Habana, Cuba, reprints in full a Spanish translation of Rucker's concise description of alas-

trim which appeared originally in the Public Health Reports of December 9, 1921. There can be little doubt that alastrim is merely an aberrant form of smallpox and it is regrettable that the word alastrim has crept into medical nomenclature, since it is misleading to the lay public which is always anxious to call smallpox. From the public health point of view any kind of smallpox is a health hazard and an economic menace, no matter whether it is called Kaffir-pox, Cuban itch or amaas and regardless of its apparent mildness. To paraphrase an overworked quotation, "Smallpox by any other name will pit as deep." The community which is well vaccinated is immune to smallpox in all its forms. On the other hand, the community which is carelessly vaccinated is unprotected and sooner or later will be visited by smallpox.

It takes an acre of ground to bury a thousand persons. What right have dead people to occupy ground which might be producing food for the living? After all isn't cremation the sanitary way of disposing of all the dead products of the community?

### Factors in the Silk Industry

The Industrial Fatigue Board of Great Britain has recently published the results of its studies of the differences existing between the outputs of various individual operatives. The rate of production was found to vary from 62 "picks" per minute, representing an efficiency of about 43 per cent, to 130 "picks" per minute or an efficiency of 90 per cent. At these rates it took one operative 318 hours to weave a warp while another required 146 hours. The employer must meet the problem of preventing the losses which occur in this way, for while the one worker receives less than half the hourly return from labor of the other, the overhead expenses run on at an undiminished rate. In order that the optimum output of the factory may be assured, it is necessary that weavers select their men more carefully and train them more efficiently. The observations quoted have shown that the essential qualities of a good silk weaver are: good eyesight, powers of observation, bi-manual dexterity, a delicate sense of touch, and an ability to stand for long periods. About two years are required to train a weaver to weave quickly and well and the report urges that in all establishments except the very small,

schools for the proper training of weavers be put in operation.

### To Find Trichosephalus

Baer in a letter to the *Lancet* (Vol. CCII, 5150, May 13-22, p. 968) recommends that the feces to be examined be placed in a black enamel dish, such as is used in photography and mixed with a little water. On stirring gently to disintegrate the feces the white thread-like convolutions may be easily discovered. For finding the eggs, add a few ccm of a 20 per cent solution of hydrochloric acid to a small quantity of feces, shake well, add a little ether and centrifuge. The eggs will be deposited.

Eleven per cent of all permanent industrial accidents involve the eye, according to Wallace of the Eye Sight Conservation Council of America, and approximately twenty-five million workers in the United States have defective vision which requires correction.

What is needed in the prevention of disease is more fresh and less hot air.

### Tuberculosis Contacts

Anyone who has taken many tuberculosis histories has been struck with the frequency with which the patient has a tuberculous parent, brother, or sister. Sometimes this is lacking, but not infrequently a history of some older tuberculous person in the family during the childhood of the patient is obtainable. In taking tuberculosis histories it is important that the presence of other cases in the family be determined and it is equally, or even more, important that the exposure of young children to an open case be determined. In any case, these facts should be reported to the health officer and he should follow up and study these contacts in their environment. Many times, it will be possible to remove young children from exposure to the disease and always it will be possible to undertake the education of the family as to the communicable nature of tuberculosis. This is an important and very necessary field for the public health nurse.

The annual death rate per 1,000 in nine cities having a population of over a million, for approximately the same periods in early 1922 was New York 14.8, Paris 14.9, Chicago 15.7, Hamburg 16.6, London 17.5, Berlin 18.3, Rio de Janeiro 22.2, Vienna, 24.6, Bombay 32.8.

## The Swing of the Pendulum in Health Education

THE teaching of physiology and hygiene in the public schools, began half a century or more ago, in large measure as a result of laws enacted on behalf of "temperance physiology." The instruction given was in most cases limited to routine anatomical detail, and was probably as unproductive as any type of teaching that was ever undertaken. It is natural, therefore, that the remarkable development in health education which has taken place during the last five years, largely as a result of the stimulation of the Child Health Organization, should have involved a violent reaction against the old-fashioned formal instruction in physiology. The keynote of the present day is habit formation, and an extraordinarily promising technic has been developed for appealing to the imagination and enlisting the interest of the child in the improvement of its own physical condition. There is real danger, however, that the pendulum may swing too far; as Professor Wilbur, of Stanford University has said, the teacher who is to do really effective work must think biologically and cause her pupils to think biologically, and not merely "put over rules." It is desirable to form health habits which will be useful at the moment, but it is also important to give the child a sound knowledge of the principles of physiology and hygiene so that in the future it can modify its habits intelligently as the need may arise. These subjects were dis-

cussed in detail during the last week of June at a conference on health education called by the Child Health Organization and the United States Department of Education, at Lake Mohonk, and during the first week of July by the Child Hygiene Section of the National Education Association in Boston. It is indeed well to emphasize the acquisition of health habits as the primary objective of health education; it is well to develop all the resources of correlation and extra-curricular inspirational technic, but it is important also to provide for sound systematic classroom instruction in the fundamental biological principles upon which healthy living must be based.

In the words of the excellent report of the committee on a School Health Program of the American Public Health Association, "The goals of health instruction are to establish health habits, to give the child the practical knowledge in the principles of healthful living, to develop health ideals, to assume a sense of individual responsibility for the health of the community, and community responsibility for the health of the individual." If these ideals can be realized as a whole the health officer of the future will have a real foundation upon which to build.

## Dietetics and World History

HE WHO would write the story of the influence of the human stomach upon the history of the world would indeed produce a work no less interesting than valuable. The tree-man, migrating with the seasons in search of food; the cave dweller descending upon a more advanced agricultural race to raid its crops and perhaps returning with women to infuse a new blood for the improvement of the racial stock; the explorations for new food stuffs, and the rise of a crude chemistry from the experiments made with strange fruits and vegetables; all of these would be included in such a history.

The discovery and exploration of the new world, largely grew out of the insatiable demand of the stomach of western Europe for a stimulant which would assist it to wrestle with the rough food of that period, and thus the craving for pepper hastened the finding and occupation of the Americas far more than the lust for gold. It was the high price of bread which precipitated the French Revolution while in America a tax on tea played an important part in the foundation of the republic. It was the starving of the reconcentrados which precipitated the war with Spain far more than the sinking of the Maine, and who can doubt that hunger, either actual or prospective,

was a far greater influence in the World War than the assassin's bullet at Serajevo?

Historians tell us that a kingly indigestion has on more than one occasion altered the destinies of nations; certainly the hunger of the Carthaginians which betrayed them to their final doom completely altered subsequent events in the Mediterranean basin. It is not difficult to imagine that a long continued diet of cabbage is the father of Sovietism or that gout has on numerous occasions produced profound effects on the "Island Empress of the Sea." Beriberi and pellagra have been the undoing of whole communities, and many historians believe that had it not been for a defective commissary and resultant outbreaks of scurvy and food poisonings, Canada would now be a part of the United States.

Since diet plays such an important rôle in the drama of human events it is highly evident that it is a factor of primary importance in the battle for the public health. This is becoming more generally realized and we are paying more attention to this vital subject than formerly. Many of our public schools now include training in cooking and a knowledge of food values as a part of the regular curriculum, while in the colleges and universities, such courses are increasingly well attended. From an industrial point of view, this is most important. The underfed, improperly nourished workman cannot adequately produce, any more than the soldier can fight long when hungry. Many of the labor troubles in lumber camps have been traced to a long continued diet of beans and who can doubt that the supreme heroism of the French so wonderfully displayed during the World War cannot, in part, at least be credited to the excellence of French cookery.

It is not enough that sanitarians shall control the epidemic infections. They must maintain their clientele in health. The practical application of the principles of dietetics on a wholesale scale is a most important factor to this end.

---

### Prison Reform and Industrial Medicine

A SHORT time ago, a distant community was shocked by the discovery of a sub-normal boy loaded with chains and kept in a dark corner by a sadistic teacher on account of an infraction of some of the school rules. Indignation ran high, the victim was freed, photographed, fed, clothed and transformed into a popular hero, while the schoolmaster was arrested, tried and imprisoned by a populace which in the incident unconsciously beheld itself in microcosm.

About the same time, a notorious young house-

breaker, a deviate kleptomaniac, escaped from a penitentiary where he was serving a fifty year sentence, robbed a house of a few valueless articles and on failing to halt at the command of a policeman, was shot and killed. The same community which was horror-stricken at the punishment meted out to a recalcitrant schoolboy, almost purred with satisfaction at the killing. If this same robber had been killed after escaping from a psychiatric hospital, where he really should have been, the act would have been viewed with repugnance, but since the prison is a place of penance, not of treatment, it was regarded as a highly laudable means of ridding society of a burden.

The parallelism in these cases lies in this. The schoolmaster was too ignorant, too brutal, and too lazy to grapple adequately with the problem of molding a defective mentality to an arbitrary standard. Similarly, society contents itself with creating and enforcing laws which relentlessly and impersonally prescribe the term of imprisonment for each crime on the category. In both cases, there was no thought of personality, treatment, or cure—no attempt to create physical, mental, or moral health. We house, feed, clothe, exercise, and moralize our social patients but for the most part we attempt only feebly at cure.

The business of treating sick bodies is a highly technical one in which no person may engage without demonstrating his fitness therefor; the mission to ailing souls may not be undertaken without adequate preparation; the straightening of strabismic minds is a work in which only the well trained may indulge; yet in many states, the only prerequisite to prison administration, a tremendously complex operation requiring an intelligent appreciation of all three specialties, is a master's degree from the school of political experience. Hence many wardens with the best intentions in the world, fail utterly to comprehend the larger potentialities of the prison as an instrumentality of cure and training.

Gradually society is beginning to demand higher qualifications of those to whom the care and treatment of its aberrants are committed and several states, notably Massachusetts and California, have made noteworthy reforms in the direction of the application of occupational therapy as a means of curing the social deviate. Little by little a body of men who have been specially trained for this work is being created and these men are blazing a trail through a forest of social cruelty and ignorance which will lead to better things. Patient research and experiment, careful study of the conditions under the work must be performed, painstaking investigation of the individual pris-

oner to determine the great underlying cause of his condition, these are a few of the endeavors which this group of workers has undertaken.

The problem is largely one of social medicine on a huge scale. It is as wide as humanity itself and it has its roots in the most remote portion of man's history. The classification of those who break the laws of society as individuals, not as a mass of perverse, deviate and subnormal minds. The application of the principles of industrial hygiene to the cure of the socially biased, all of these are but the manifestations of the way that industrial hygiene is creeping into the problem.

So far as the sanitary and medical phases of prison administration are concerned, the problem has been pretty well met in the sense that cleanliness, ventilation, safe water and the proper treatment of intercurrent diseases and injuries have all been insisted upon, but for the prison physician himself relatively little has been specifically done by the rest of the profession of medicine. There does not seem at first glance to be any particular niche in the various technical medical societies for him. Why not create a place in industrial medicine where his wealth of valuable experience will add to our learning and be a great inspiration?

---

### Health and the Physical Plant

**I**N VIEW of the implications bound up in the sanitary administration of the individual household it is hard to explain why cleanliness is usually regarded as a matter of ethics instead of a habit of living fundamental to health. Full value must be given to the fact that individual standards of cleanliness are not ingrained, but are the casual product of environment and circumstance to account for the necessity of somehow inducing the individual to clean up his own door yard before he can be counted upon to support a wider application of sanitary practice in municipal housekeeping. Social workers, who continually find health questions inextricably bound up with conditions in the home, often secure their best corrective measures through the administrations of a visiting housekeeper, and the greatest tax upon their ingenuity is encountered in the effort to institute a régime of cleanliness where the conditions of the "home plant" are archaic and unfavorable or where crowding makes decent living difficult.

We all know that if the world is to lend itself to reform, it must be made to see its duty in ways that are pleasant; but is thoroughgoing sanitation to be practicable only in the spacious home on the one hand, or the multi-family house on the other? In organizing a technical service to the small

home builder recently the American Institute of Architects admitted their collective responsibility for the fact that less than 3 per cent of the small homes in the country are properly planned or adequately supervised from a structural standpoint, not to mention such engineering problems as the place of the small house in city planning; light and air in the home; cleanliness in the home, involving protection against dust and smoke, water supply, waste removal, etc.; construction to avoid dampness, or to protect against vermin, or to eliminate such "conveniences" as the insanitary garbage chute.

Much has been said about the unappreciated bath tubs in tenement districts, but one hears nothing of the discouraging effort of a housewife to mitigate the evils of wrong or insufficient installations of one kind or another, or of the impossibility in health work of countering the deleterious effects of defective drains. Municipal sanitation is a major issue; industrial hygiene has its place; but no question can be considered more vital than the rational equipment and organization of the small home for easy and efficient sanitation.

---

**A** SCHEME of maternal welfare is outlined in the report of the Joint Committee on Maternal Welfare of the American Gynecological Society and the American Association for Child Hygiene. Five main lines of inquiry were pursued by the Committee: (1) The elaboration of a complete scheme of maternal welfare, emphasizing the idea of educating the public to the necessity of this work; (2) the relationship of this work to other health and welfare activities such as infant and child welfare, the venereal disease campaigns, board of health, social agencies, and certain eugenic problems; (3) representative conference with governmental agencies on the larger aspects of the question; (4) the development in cooperation with pediatricists of child welfare work on the basis of maternal protection.

The problem of maternal welfare is a public health problem and cannot be considered apart from its public health aspect. It is, however, definitely a matter for expert study and becomes properly the concern of gynecologists and of pediatricians. Approached in this way, fuller reports will serve the public health officer, and more scientific study will serve both medicine and eugenics. No one can regard the situation in this particular field with any complacency and its extensive study in its various relationships to other phases of preventive and curative medicine is a much needed contribution.

## Sickness Records in Preventive Work\*

Prevention, of Course, Presupposes an Exhaustive Study of the Conditions to Be Prevented

BY EDGAR SYDENSTRICKER, STATISTICIAN, UNITED STATES PUBLIC HEALTH SERVICE, WASHINGTON, D. C.

IN INTRODUCING the subject of the use of morbidity records in the prevention of disease I can do no better than reiterate, with as much emphasis as possible, this broad principle: *That intelligent health administration in the industrial plant, as in the community, of necessity rests upon a knowledge of what ill health exists and of the conditions under which it occurs.*

There will be no dissent, I take it, from that principle of common sense, but there undoubtedly is a failure on the part of health administrators to appreciate the value of accurate and complete knowledge of the incidence of ill health in its various manifestations. They are too apt to rely on unsystematic, irregular, and incomplete observation. More than one medical director who has efficient systems of entrance physical examination, emergency relief, and hospitalization, has rejected the idea of sickness records with the remark that any case of illness quickly comes to the attention of himself and his staff and that records are unnecessary.

Now if the industrial medical director is to be a health administrator in the preventive, in the real sense of the term, and not merely an emergency surgeon or rest room doctor, there is no easy escape from the necessity for an adequate equipment of morbidity facts. No degree of pro-

*If preventive work in industry is to become effective, the industrial physician must be a first rate epidemiologist, and if he is an epidemiologist at all, he must establish an adequate system of morbidity statistics. The more complete the reports of illness, the more specific the service it is possible to render.*

*No degree of proficiency in the practice of his art; no amount of erudition in theoretical medicine; no boasted expertness in management of clinic or hospital will serve the physician in prevention without continuous concise knowledge of the ill health that exists in the plant, and the specific conditions under which it occurs.*

iciency in the practice of medicine, no amount of erudition in the many subjects allied in the prevention of disease, or of expertness in the management of relief stations and hospitals, or of sympathetic care of the group or of devotion to individual cases, can avail fully unless he has also the means of knowing, and does know, what ill health exists and the specific conditions under which it occurs. He must, in fact, be an epidemiologist, in the broad meaning of the term. And since the conditions he must deal with are intertwined in a maze of interre-

lations, and because he must account to a keen appraisal of his results, he is called upon to be an epidemiologist of a different sort from the most of us who are trying to do something in that field, and, I am impelled to believe, he must be one of a higher order.

While the industrial medical director is a sanitarian in just as true a sense as the government official, and while his responsibilities to his own population group and to the industry are of the same kind as those resting upon the municipal health officer, the vital statistics and disease records which constitute his epidemiological tools of necessity are of a different character. Of mortality records he has little use, and of reports of communicable diseases ordinarily on the health department's list of notifiable diseases he has relatively little need. He is more concerned with indicators of health, with records that are far more delicate and responsive measures of deviations from good health than the registration of deaths or of certain epidemic diseases. The short illness that can be described only in terms of a symptom is a fact of great importance not only because it results in loss of efficiency but because it is a symptom and, if recurring, may be a sign of serious deviation from health. Ailments and diseases that do not come to the notice of the municipal and state health officer are the principal objects for preventive work by the industrial physician. Again, while

\*Read at the Seventh Annual Meeting of the American Association of Industrial Physicians and Surgeons, St. Louis, Mo., May 27-28, 1922.

the public health official relates the incidence of disease and death to only general conditions unless he is making a special epidemiological study, the industrial physician must relate the incidence of symptomatic ailments and of disease to as specific conditions as he can in order to make his preventive work immediately effective.

If we agree that the industrial medical director should be equipped with this sort of knowledge, and proceed to the further consideration of the matter, two questions suggest themselves: What facts, specifically, should be made available? And, what are practicable means for rendering them available?

The specific nature of the information desired must, of course, be determined largely by the individual medical director in accordance with his particular needs, but there are certain considerations which I believe are applicable to any system of sickness records and which our experience has shown are fundamental if the records are to have a value in preventive work.

Briefly stated, these considerations are:

(1) In any system of sickness records provision must be made for expressing the incidence and prevalence of a symptom, of a disease in terms of *rates*. This may not be necessary for the tabulation of disease incidence for current purposes since the size of the plant, or the number of persons employed in a given department or occupation is kept in mind; but it is essential to any statistical analysis. A simple statement of this principle may be made as follows: That every provision made for classifying cases into nativity, sex, age, occupational, or other groups should be accompanied by a similar provision for classifying all of the employees for whom case records are available in order that the incidence of ill health may be expressed proportionately to the number exposed to a given condition or set of conditions.

(2) While a "standard" form for recording ill health is impracticable yet there are certain basic items of information without which no analysis can be complete enough to warrant dependable conclusions. These items classify themselves into three kinds, namely: (a) Items relating to the individual and affording the basis for the proper grouping of individuals according to inherent differences, such as nationality, nativity, or race; sex; and age. (b) Items relating to the conditions under which the individual

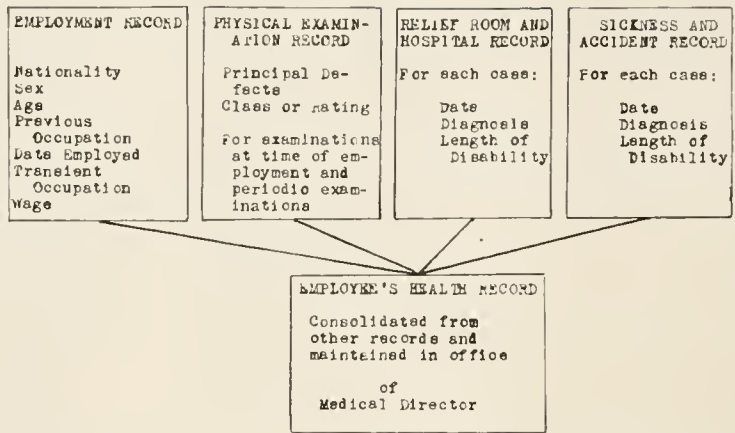

Fig. 1. Where three or four separate records are kept in as many different departments—employment, physical examination, relief, and hospital—the data are to be brought together on a single card, the consolidated card linking together the information necessary for the health administration of a plant.

works and lives such as occupation, department; wage rate or earnings, as indices of economic status. (c) Items indicating the physical condition and health of the individual, such as—occurrence of symptoms of ill health, disease incidence, physical defects as ascertained through examination, and absence from work on account of sickness.

#### Continued Observation

To these may be added a fourth group of items if it is desired to measure the effects of ill health in such terms as production, loss of working time, irregularity in attendance, loss in wages, etc.

(3) The scientific, the common sense method of finding out what effects various conditions have upon the health of the worker is that of *continued* observation of the worker under those conditions, using the record of his deviations from good health as the measure of the influence of the conditions themselves, after taking into account such factors as race, sex, and age and certain conditions of environment. In such a procedure we adopt the essential principle of sound laboratory theory and practice and, although conditions can not be controlled to the same extent as they are in laboratory experimentation, it should be rendered increasingly practicable to observe the effects of specific conditions while at the same time evaluating statistically the effects of other conditions. Much emphasis has been given in recent years to the "cross-section" or the survey method. A plant is "surveyed" in order to find out what hazards to health exist, but the judgment of whether a condition is "good" or "bad" is based on experience elsewhere, or too often on theoretical and general grounds. Groups

of men are given physical examination and placed on jobs usually upon rather general considerations, or conclusions are drawn from the presence of specific defects as to the effect of occupation. I can not but believe that, because of inadequate data and at times unsuitable methods, conclusions have been reached that have been unjust to the industry and, on the other hand, probably serious conditions have been overlooked, because we have not used the right kind of methods for discovering them.

The continuous record of the occurrence of ill health for each employee is an important step toward affording such a method. It is in line not only with principles of scientific research but it is essentially the physician's way of keeping track of his case. It is sound and, we believe, thoroughly practicable.

(4) The sickness record of an employee is a dependable measure of his health provided, however, that illnesses of *short* duration be recorded, even though some diagnoses be statements of symptoms only.

In one large company the annual sickness rate was 1,573 per one thousand employees when all sicknesses lasting one day or longer were included, but the rate was 317 per one thousand when only sicknesses lasting seven days or longer were included. Eighty per cent of the disabilities would not have been noted if the records omitted those of less than seven days' duration.

Two large plants, one recording sicknesses resulting in not less than one day's absence from work and the other recording only sickness of seven days or longer in duration, showed the following experience for a year:

Plant "A," recording only sickness

Fig. 2. A mass of records of this kind will afford an adequate basis for statistical analysis of ill health and loss of time resulting. They will afford comparisons as to age, sex, race, and will give the necessary information as to cost of preventable disease and the cost of prevention.

lasting seven days or longer showed a rate of 120 per 1,000 employees, while Plant "B," recording all sickness over one day's duration, showed a rate of 1,990 per thousand employees.

The shorter the illness which is recorded with a diagnosis or a statement of symptoms, the more specific is the sickness record. The sickness record thus becomes a continuous case record for the individual employee. For a group of employees working under given conditions such a record furnishes a series of observations on the reaction of the individuals to those conditions. For example, comparing Plants "A" and "B" again:

return in actual knowledge gained. In some industrial establishments when a real effort has been made to inaugurate morbidity records the mistakes have been made of going into too great detail for obtaining current information and of making too many tables. This is largely the result of a failure to keep in mind exactly what the records are for.

Summary of Suggestions

The completeness of our charts and the magnitude of our mass of tables do not indicate in any sense of the word the real value of the data. I would say that the surest way to destroy anyone's faith in statistical data is to overwhelm him with charts and tables that do not mean anything definite and worth while from the point of view of the real problem at hand.

Is it practicable, granting that they are desirable and even fundamental, to put these things into operation?

The best answer to this question probably is the simple statement that they are already in successful operation in some establishments where the medical directors have realized the need for an adequate method of keeping track of the health of the employees and have realized also the scientific value of records such as these. After three or four years of study of various systems of records we do not believe that a standardized system, with standardized record forms and standardized items of information, is practicable unless it be for the different plants operating under a single management. Nor do we believe that such a degree of standardization, even if possible, is neces-

Disability	Plant A Only sicknesses lasting over 7 days recorded	Plant B All sicknesses lasting 1 day or longer recorded
Colds (86) .....	0.0	197.8
Bronchitis (89, 90) .....	8.4	42.6
Pneumonia, all forms (91, 92) .....	4.8	6.7
Tonsillitis and other diseases of pharynx (100) .....	7.7	195.9
Stomach disorders (102, 103) .....	1.4	83.1
Headache (189) .....	0.0	88.1

In Plant "A" the sickness record is of little value except for serious illnesses.

It approximates a mortality record rather than a health record.

(5) Simplicity in the recording and analysis of the records: The fewer the facts and the more significant these facts are, the greater will be the

sary or even wise. We do feel, however, that the following suggestions are practicable and would yield as good results to industry at large and better results to the individual medical or service department.

First, that the medical director of an industrial establishment profitably may coordinate the employee's records already existing and make them a part of his health record, adding to the existing records an adequate record of disability due to sickness. In other words, he can utilize to a far greater degree than he does now the records already available and he can render them infinitely more valuable by possibly slight additions or modifications. Many plants which maintain medical services now keep three or four separate sets of records—employment, physical examination, relief (and hospital), and sickness and accident—for each employee. The employment record usually contains the essential information for the statistical classification of employees into the nationality, sex, and age groups; the other records contain information relating to his physical status and to his health. If they can be coordinated in some such way as I have suggested on the accompanying diagram (Fig. 1) and card (Fig. 2), the medical director will have for his use a health record for each employee on a single card. It will be noted that such a record (1) links together the facts relating to the physical status, occupation, sickness and accident experience, and loss of time for each employee on the same card; (2) enables the medical director easily to pick out the employees who need especial attention or change in job, or both; (3) affords an adequate basis for statistical analysis of ill-health and loss of time resulting therefrom according to cause for employees classified according to occupation and in comparable sex, age, and nationality groups, when such an analysis is advisable or necessary; and (4) can be adapted so as to afford the necessary data as to cost of preventable diseases for comparison with cost of prevention.

Second, there will develop gradually a standardization in definition of terms and in the items of information recorded if some slight machinery is afforded for associating those who are working in this field. There is already a pressing need for a standard classification of the causes and symptoms of sickness. There is already expressed on the part of many medical directors a hope that "normal" sickness expectancy, from all causes and

for specific causes, can be worked out in order that comparisons can be made with actual experience. But these things can come only as experience accumulates. If through some concerted action the medical directors of even a few plants can cooperate in a small number of essentials, the rapid accumulation of experience will be along more definite lines and will be more useful to all concerned.

Lastly, no discussion of industrial sickness records should be closed without a reference to the very great con-

tribution they can be to the scientific study of the causes of ill health and to the prevention of disease. Do you know that even in this enlightened age there are only a bare half dozen diseases about which we know anything as to their true incidence and prevalence? We have mortality records, such as they are, of the diseases that result in death, but we do not know the extent to which diseases that do not result directly in death, but do cause suffering and loss of efficiency, actually prevail. We are grop-

ing in the dark yet in these matters.

Some of these days the problem of public health is going to be defined in different terms, when we know what and how much ill health—not mortality—prevails under different conditions. And the industrial physician, with his invaluable records of the health of thousands upon thousands of individuals, is, I feel sure, going to make one of the most important, if not the most important, contribution to a scientific diagnosis of the health of the people.

## Factors Determining Length of Work Day\*

### Task System and Internal Drive to Work Possible Solutions of Problem

By REYNOLD A. SPAETH, PH.D., SCHOOL OF HYGIENE AND PUBLIC HEALTH, JOHNS HOPKINS UNIVERSITY, BALTIMORE, MD.

THE length of the work day appears at first as a problem of amazing complexity. At the outset, the questions arise as to how long can a man work or how long *should* he work. In the end, it resolves itself into the problem of how long *will* a man work. Our viewpoint of the crux of the problem presented by modern industrial conditions is best summed up by the old proverb, "You can lead a horse to water, but you cannot make him drink."

In considering the purely scientific problem of actual physical performance of men and women under industrial conditions, we find that their performance varies with (a) the nature of the work, and (b) the nature of the worker. The industrial investigations that were made during the war, especially in England, have given convincing statistical evidence that when output is plotted against weekly hours of work, the graph slopes to the base line on either side of the optimal peak. In other words, there is a point beyond which output *falls* whether hours are increased or decreased. In general, it is safe to say that the chance of reducing hours without reducing output is directly dependent upon the percentage of human energy expenditure in any particular job. For example, Dr. Vernon found that in the heavy, strenuous task of sizing fuse bodies, the output of men was increased 22 per cent by reducing hours 12 per cent. In a second case, this time of women engaged in

moderately heavy work, a 9 per cent rise in production followed at 31 per cent reduction in hours. Reducing hours becomes less economical as semi-automatic or automatic machinery more and more determines the speed of an industrial process. Thus, women employed at the light work of milling screw threads, a process where for four-fifths of the time the operatives may stand or sit idly watching their machines, had their output reduced 1 per cent by a 25.9 per cent reduction in hours. With a nearly straight machine process when hours were reduced 24.8 per cent, output fell 3 per cent.

#### Primitive Stimuli to Work

The striking thing about these figures is the tremendous disparity between the percentage reduction in hours and the change in production. Even when due allowance is made for the fact that these production figures were obtained under the abnormal emotional stimulus of war, it is clear that there comes a point beyond which it pays neither the employer nor the employee for the latter to stay on the job. In the automatic and semi-automatic machine processes, this optimum point lies between a nine and ten hour day. As work becomes heavier with a longer "handling time," the optimum shifts towards the shorter day of seven or eight hours. If Vernon's figures are accepted as representing a universal truth or even a tendency, we must conclude that it pays the employer to have machine operatives on a nine or ten hour basis. Considered then as a part of the mechanism of

industry, machine employees can be worked ten hours a day profitably to the employer, and, so far as scientific methods have been able to determine, in most cases without physical injury to themselves. Whether this conclusion can be wisely applied from any viewpoint except that of immediate profits to the employer is another matter. From the viewpoint of the employee, a machine that does the work of ten men and needs but one operative forces a longer schedule of hours on that single operative at the same time that it throws nine men out of work. What, exactly, does the employee get out of it? He gets the advantage of lightened physical labor; but he is absorbed relentlessly into the machine, becoming a part of its mechanism.

It is scarcely necessary to discuss in detail the importance of physical job-conditions and the part they play in determining output. The importance of adequate illumination, humidity, temperature and seating facilities have lately been studied in great detail. The physical aspects of the work-day problem involve, on last analysis, the discovery of the most efficient relation between work periods with their resulting fatigue and rest. It follows that any factors which contribute to the production or elimination of fatigue must play an important rôle in the problem of optimal industrial performance.

Assuming that ideal physical working conditions have been secured; that the physical condition of our personnel has been examined; and that so far as practicable a job and man have

\*Read before the Fifteenth Conference of Pennsylvania Industrial Physicians and Surgeons at Harrisburg, Pa., May 25, 1922.

been brought together by the use of the various predictive psychological methods, we find that if an organization is really to be a successful, going concern, it must have a combination of subtle psychological influences, involving both the incentives to work and the mutual attitude of men and management. This phase of the work-day problem is so important and has been so largely neglected in practice in the past that it will repay closer examination.

The stimuli that urge men to work fall roughly into two groups. The first and more primitive is the fear of privation and death. Self-preservation is a deep-seated instinct. Man must eat, and he will work at least enough to secure food. At the bottom of the scale of wage earners is the stake-worker and hobo, a sort of social manic-depressive. He works until he has enough to live on for a short time and then quits, only to work again when his "stake" is gone. The reward here is existence plus a few simple pleasures, perhaps even the beginnings of luxuries. The extent to which money will *drive* men to work is largely limited by their imagination, cultural level and social responsibilities—wives and children. During the war there were numerous instances of financial saturation when certain expert craftsmen preferred to work but three days a week and lie abed the other mornings revelling in the mere sensations of opulence.

Money, then, for the sake of gaining the necessities and the simple luxuries of life, represents the most primitive stimulus to work. It is even more powerful as an indirect one. Its possession leads to distinction; and all men of imagination desire distinction and its recognition by their fellows. Closely associated with the desire for distinction, is the desire for power over the lives of others. At this point, the element of compulsion ceases to be external and superimposed; we are now dealing with our second group of incentives, internal, spontaneous, and astonishingly effectual.

The spontaneous, internal urge on the part of professional workers—physicians, teachers, lawyers, scientific investigators—is a well known fact. The professional man or woman's workday is limited only by opportunity, on the one hand, and considerations of health, on the other. Call it interest or curiosity in his fellow men, their relations with each other or their environment, there is present some sort of internal drive that operates almost completely independently of external compulsion.

The two factors of working essentially for his personal advantage and a continuous sense of progress, play an important rôle in the professional man's driving mechanism.

### Inner Drive, Not Compulsion

The internal drive on the part of the craftsman or the industrial worker is less understood. Too often its existence is doubted or even denied. The present "open shop" drive, however cleverly its organizers rationalize truth into obscurity, is backed by the conviction that only by the application of stern external compulsion can men and women be got to work. It is true that if you can force workers down and keep them down near a bare subsistence level, using the whip of unemployment to keep the regulation of wage rates strictly within the employer's grasp, you can force them to work in order to live; and you can then determine a suitable length of the work day for them as human machines, balancing physiological needs, job conditions, time worked, output and profits; or you can burn them out like electric bulbs and get new ones when you need them. But, in the first place, you will waste an enormous amount of energy in getting and keeping the workers with imagination and will power "in their places;" and, in the second place, they will fight you constantly with your own weapon, external compulsion. By strikes and "labor troubles," by direct sabotage, and "conscientious withdrawal of efficiency," the worker today expresses his rebellion against being held to a level that no longer satisfies his imagination. With compulsory education, cheap transportation, movies, and crowding into cities, the industrial worker of today has become a person with whom to reckon with something more than external compulsion whether the employer likes it or not. The method of compulsion from without is, to a large extent, simply outmoded; it is economically and psychologically unsound.

There remains to release and make operative the internal compulsion which is analogous to the internal drive that spurs on the professional man. We hear of the "instinct of craftsmanship"—the "will to work." Whether or not we understand it, it exists. There is really no miracle connected with those occasional and mysterious cases of industrial tranquility where an extraordinary spirit of loyalty and cooperation in industry takes the place of labor troubles. It is worthwhile to examine those estab-

lishments that have avoided strikes and disputes; that have maintained not only their output but also the enthusiastic cooperation of their labor force.

One finds in these plants a complete absence of paternalism and a form of "scientific management" worthy of the name, an application of common sense combined with a knowledge and understanding of human behavior. Wherever possible, the decision and responsibility for such matters as distribution of work and length of work day are shifted, to a large extent, on the shoulders of the employee. Native executive ability and personality are permitted to make themselves felt. By regulating within limits their own hours of work and rest, an interest at least in the organization of their work is permitted to the workers. Frequently in these plants the employers take advantage of a deep-seated human tendency to idealize a personality. They build their organization or its departments around one well chosen man. He becomes a local god. He is honest and square; he can do no wrong. The employees believe in him and through him in the management. In short, successful and modern industrial organizations are exploiting undreamed-of sources of industrial tranquility by the intelligent releasing of an inner compulsion to work. Once we discover the particular combination of physical and psychological conditions under which men and women are most willing to work, we may then ask how long should they work.

An instance of internal drive, interesting because of the modern touch, is that of a small girl whom I saw in a rubber-shoe factory two years ago. This child was seventeen years old and worked on a task basis. She could complete seventy pairs of rubber shoes by hand per day. I watched her work for a long time. I learned that she came into the plant at seven o'clock, got on the job at once, had all her materials laid around her according to the best scientific management which she had devised herself, and worked until 1:30 or 1:45 p. m. She would not talk to me. She was too busy. I asked her sister what the drive was that made her make this production record, and the sister said: "She has to get to the movies at 2 o'clock." Here we had a novel incentive in the case of this child who felt that she had to get her job over if she wanted to get to the movies on time.

If we consider the variability of human beings, it seems to me that some kind of task system has much

to recommend it. I believe that this is more logical than a fixed hours of work program; because to let all work with a rapidity in proportion to their skill and ability, and let them quit when through, would supply a tremendous incentive. The danger, of course, is that the task might be unduly increased without an increase in wages, and that this would lead to soldiering. We cannot go into the subject of soldiering which was the original difficulty at the Midvale Steel Company. The men found that when they had once made a high record, there was no chance to go back to less efficient production and that their wages were not correspondingly increased.

During the past century, the work day has been gradually shortened from sixteen to six hours. The reason was fundamentally economic. It was good business to shorten the work day. Perhaps I am not too optimistic in saying that I believe I see an eager appreciation on the part of the employers of the value of cultivating this gold mine of energy that is available, instead of using the old drive of compulsion from without, by spending

their efforts on that of compulsion from within. If employers will turn to the much more profitable field of developing this enormous source of energy of compulsion from within, the work-day problem will have lost much of its present seriousness.

#### Discussion

Miss Mary Van Kleek, Director, Department of Industrial Studies, Russell Sage Foundation, New York City; The Department of Industrial Studies of the Russell Sage Foundation is making a study bearing on the question of hours of work, results of which are not yet completed but the method of which may prove interesting. Shortly after the plan was put into operation in a certain plant by which the workers have representation on the board of management, that board voted for a decrease in the hours of work from nine to eight; and the workers, at the same time, urged that time clocks be installed and made a number of suggestions as to the way in which efficiency could be increased to make up for the shorter hours. The processes of cotton bleaching used in the plant were not changed during this period, and we are taking the actual output obtained from men who are in each department for certain months of 1918, 1919, 1920 and 1921, believing that we could make the estimations over the war period and immediately afterwards. Besides the simple relation between hours of work and output, we had to go into all the problems of management, not only in the plant as a whole, but also in each department. It is not safe to base conclusions on anything other than an adequate basis of facts and which include not merely the information about output and hours, but include all the other psychological factors, the attitude of the workers, and all the factors entering into their working relationship.

## Safety Code for Elevators

NOT one person in a hundred ever considers the amount of "vertical" transportation handled in a large city. The elevators in the large office buildings, hotels, apartment houses, department stores, and mercantile establishments handle in a city the size of Philadelphia or Chicago as many people as are carried on all the subway, elevated, and surface lines combined.

Governing this great transportation system, American engineers have devised a safety code to safeguard the millions carried daily by the Nation's elevators. The code is the result of the work of more than five years, during which industrial boards and commissions of many states, the United States Bureau of Standards, the American Institute of Architects, insurance companies, and manufacturers cooperated with the Committee of the American Society of Mechanical Engineers.

The code consists of seven parts, involving hoistway construction for passengers and freight elevators and for dumb waiters, power passenger elevators, power freight elevators, hand elevators, and hand invalid lifts, escalators, and operating rules. Commenting on the Code and its preparation, the *New York Times* says:

Reduction of accidents with their heavy toll of human life is the aim of the Elevator Safety Code.

The larger a city is and the more congested the business district, the greater will be the number of elevators per thousand population," said the society's statement. "Safe as modern elevator travel is, there are still a large number of elevator accidents. The number of fatal accidents throughout the country reported by press clipping bureaus for a period of five and one-half years was 978, while the non-fatal accidents totaled 1,386.

It is safe to assume that the total accidents in the entire country during this period was at least twice this number. In New York City alone, according to the Coroner's records, there were killed not less than 721 persons in a period of two years inclusive, while Chicago lists 401 fatalities for a period of thirteen years.

Contrary to popular opinion, only a very small percentage of the total number of accidents are due to the dropping of the elevators. Certainly not over 6 per cent are attributable to this cause. Modern safety devices and higher factors of safety for cables have practically eliminated falling cars as a source of accident.

Approximately three-fourths of the fatal and the serious non-fatal elevator accidents in the United States occur at the hoistway doors, and, strangely enough, these accidents are almost evenly divided between the classifications: "Falling down the hoistway" and "Crushed by moving

car." Practically all such accidents may be eliminated by the installation of interlocks, which will prevent the movement of the car while the hoistway door is open or unlocked, and will hold the hoistway door locked when the car is not at the landing. The safety code for elevators issued by the American Society of Mechanical Engineers urges the use of such interlocks on all passenger elevators.

Baltimore will probably have the distinction of being the first city to pass an elevator ordinance based upon the code of the American Society of Mechanical Engineers. Several states are revising their elevator codes, which are reflecting the tendencies of the engineering code, in accord with which are the New York code and the proposed code for Pennsylvania. The Detroit City elevator code ordinance prepared by J. A. McCabe, a member of the Conference Committee of the American Society of Mechanical Engineers, contains many of the provisions of the Engineering Society's code. St. Paul is another city which is affected by the new regulations, which have been adopted by the state of Oklahoma and are being used as a basis by most of the states and municipalities when the question of elevator code revision comes up. Massachusetts and California are likely soon to adopt many of the code's provisions, which recently have been embodied in a Utah revision.

The code is already exercising a strong influence in other countries. In Japan, in the nations of South America and in the Philippines it is being seriously studied.

The entire subject of eye hazards in industrial occupations and the means of reducing or eliminating those hazards will be thoroughly discussed and brought up to date in a revised edition of Bulletin No. 12 of the National Committee For the Prevention of Blindness. The regulations of the recently developed Safety Code for the Protection of the Heads and Eyes of Industrial Workers, sponsored by the U. S. Bureau of Standards and approved by the American Engineering Standards Committee, will be included in the revised bulletin. There will also be published in this bulletin illustrations of the most modern types of head and eye shields and goggles.

The Florida East Coast Railway cooperating with the Florida State Board of Health has adopted the industrial plan for fighting venereal diseases. The program calls for the erection of sign boards at the six division points of the road on which will be placed exhibits prepared by the American Social Hygiene association. Lectures and motion pictures will also be used.

# Some Industrial Phases of Tuberculosis\*

BY FRANK A. CRAIG, M.D., THE HENRY PHIPPS INSTITUTE OF THE UNIVERSITY OF PENNSYLVANIA, PHILADELPHIA, PA.

**T**UBERCULOSIS is undoubtedly one of the most important problems which today confront those interested in the public health and welfare. Numerous investigators have devoted a vast amount of attention to the methods to be employed in the prevention of this disease, the question being considered from almost every conceivable angle. There is no more important aspect of this entire subject than that which deals with the relationship between this disease and the industrial worker and his environment. Until a comparatively recent time the campaign of prevention was chiefly directed toward the eradication of disease from among the very poor, for it is in this group that the disease is most widespread and causes the greatest amount of suffering and loss of life.

Within recent years more attention has been paid to the study of this disease among that extremely important social group, the industrial workers, and a greater effort is being made to bring about a reduction in the incidence of the disease. While perhaps not quite so prevalent in this body as among the very poor, the industrial workers constitute such a large proportion of the population and are such an important factor in the welfare of the nation that special importance is attached to the occurrence of the disease in this group.

There are several features of the industrial aspect of this general problem which call for special consideration, because, while every measure instituted for the welfare of the public at large exerts a favorable influence upon this special group, the industrial workers are exposed to certain risks and factors which are peculiar to themselves, and which are not reached by any measures directed toward the prevention of the disease among the general public. If the tuberculosis campaign is to attain its object these special features must be taken into account, and adequate preventive measures devised and put in operation.

Before it is possible effectually to handle the industrial phase of this problem it is essential that we secure reliable information concerning the actual incidence of the disease

among the workers in the different industries, and, more especially, in the different occupations involved in these industries, as nothing can be more misleading to those interested in the relation between the occupation and disease, than the employment of such vague, general terms as hatter, steel workers, etc., to designate the work performed by the individual. A thorough knowledge of the disease as it affects those engaged in definite trade processes must be obtained if it is to be attacked in an intelligent and efficient manner.

## Records Are Inadequate

To secure this knowledge it is necessary that a more careful and systematic method be devised for recording the incidence of disease among the workers, and so perfected and extended that it will include not only the large plants with their well organized and effective medical department, but also the smaller plants or shops with only a relatively few workers and little or no medical supervision. Until such a comprehensive system can be devised much can be done toward its development by the compiling and standardizing of the records in the industrial plants which are at present equipped with a medical service. Most of the reports published by industrial physicians at the present time are so lacking in uniformity in their methods of tabulation and their standards of defects vary so greatly that they are almost valueless for comparative sta-

1. Craig, F. A.: "Tuberculosis As It Affects the Industrial Worker." Read before the Section on Industrial Medicine and Surgery, the College of Physicians of Philadelphia, to appear in the American Review of Tuberculosis.

tistical purposes. A recent attempt to compile the available data on the incidence of tuberculosis among industrial workers<sup>1</sup> was practically valueless owing to the absence in most cases of any statement of the diagnostic standards upon which the figures of the various observers were based, and the lack of specific mention of the various occupations involved, the method of examination, and such important additional data as sex, age, etc., of those examined.

While accurate information in regard to the prevalence of the disease is essential for a complete and efficient campaign against this disease, there are certain measures which may in the meantime be employed with advantage by the industrial physician in his efforts to check this disease. Before considering these in more detail as they apply to the industrial problem, it may be of interest to outline briefly the plan employed at the present time in the general campaign against this disease, as it is along these same lines that the industrial program will have to be formulated.

The prevention of tuberculosis has been carried out along two main lines, which may be termed: (1) the prevention of infection; and (2) the prevention of disease. Under the first heading may be included all those measures which are concerned with the dissemination of the tubercle bacillus; such as the prevention of promiscuous expectoration, destruction of the sputum, isolation of the infective case, early recognition of the disease, and similar procedures, dependent upon the education of the public for their successful application.

TABLE I.—SANATORIUM OF TUBERCULOSIS DISEASE\* COLLECTIVE DATA, 1909-1919 AMERICAN AND CANADIAN EXPERIENCE.

Condition at discharge	Condition at entry					
	Incipient cases		Moderately advanced cases		Far advanced cases	
	No.	Per cent	No.	Per cent	No.	Per cent
Apparently arrested .....						
Improved .....	5,373	34.0	1,162	4.1	134	0.5
Quiescent .....	3,983	25.1	11,308	40.2	7,116	28.0
Unimproved .....	4,739	30.0	9,572	34.0	2,236	8.8
Died .....	1,623	10.3	1,958	7.6	7,563	29.7
	89	0.6	1,138	4.1	8,405	33.0
Total .....	15,807	100.0	28,138	100.0	25,484	100.0

\*Read before the Seventh Annual Meeting of the American Association of Industrial Physicians and Surgeons, St. Louis, Mo., May 22-23, 1922.

\*Based on Chart showing general results of sanatorium treatment in 69,500 cases, regardless of length of stay or method of treatment. Published by the Prudential Insurance Company of America. Journal of the Outdoor Life, January, 1922, p. 30.

The second division includes those means which have to do with the raising of the standard of living and health of the individual to such a point that, even in cases of infection, the disease will not develop owing to increased resistance to the tubercle bacillus. We have no means at our command to increase this resistance which can be compared to the results obtained by an improvement in the general health and well being and the maintenance of this state. The successful application of the principles involved in this second division depends upon the improvement of the general living and working conditions; good food, and all that this phrase implies; proper and sufficient recreation; the prevention of other diseases and the correction of all defects; proper medical care and attention during pregnancy, illness, and following accidents; and every similar measure which will add to the general health, strength, and well being of the individual.

The application of these general principles to the special field included under the name "industry," would suggest the formulation of the following program:

### Health Talks

Health talks to the employees should include such subjects as would cover the general hygiene of the body, including cleanliness, care of the teeth, exercise, rest, food, fresh air; and the importance, means of prevention and general rules of treatment of numerous diseases. The talk on tuberculosis should emphasize the means by which the disease is spread and methods for its prevention, calling to their attention the dangers of careless spitting, sneezing, coughing, etc. The importance of having the disease recognized in its early stages should also receive special consideration, not only because early diagnosis favors the patient's recovery but also because the disease can at that time frequently be arrested before the individual becomes a source of danger to those with which he is associated at home and in the shop.

The talks may be delivered in the form of lectures, placards, leaflets or articles in the house organ, or small exhibits and moving pictures may be employed to bring the facts to the attention of the workmen in a forcible and striking manner. The local tuberculosis societies, where such exist, may be relied upon to assist in this work.

For the successful prevention of tuberculosis it is imperative that

these talks should not be confined to the discussion of the means to prevent the dissemination of the tubercle bacillus, but, as already outlined, should include instructions in general hygienic measures.

In the industrial plants these talks might be augmented by such subjects as accident prevention, or the interest of the workmen stimulated by selecting such topics as are of special importance in the individual plant, emphasizing those occupational diseases which may possibly be peculiar to that industry.

While reference has been made to the workmen in all the foregoing statements it is equally important in the conducting of such a campaign that the employer of labor be also educated along these lines of public health. It may be that the campaign must first be directed toward this individual or group of individuals before it will be possible to carry it out in the plant. To bring this effectively to the head of the plant, personal interviews will be absolutely essential.

Aside from the educational campaign outlined above the chief interest of the industrial physician lies in the early detection of tuberculosis among the workmen. This is so important and presents so many interesting problems that it will be considered in more detail than has been accorded the other phases of this general subject.

If the campaign against this disease is to be effectual and meet with the success that our efforts should encounter, it is absolutely essential that the cases be discovered while still in the early stages. There are several reasons why this point is so important. In the first place, if the disease can be recognized before there is any extensive breaking down of the process and arrested in this stage, it is possible to prevent infection of the other workmen who come in contact with the individual affected. Second, it is equally essential from the standpoint of the workman himself.

The preservation of the working capacity of the individual affected, or possibly even his life, is almost absolutely dependent upon the early detection of the presence of disease. This fact is well illustrated by the chart recently published by the Prudential Insurance Company of America,<sup>2</sup> based upon a study of 69,500 cases, showing the results of sanatorium treatment in cases with varying degrees of involve-

ment. Among the incipient cases, in 34.0 per cent the disease was apparently arrested; in 25.1 per cent it was improved; in 30.0 per cent it became quiescent; while in only 10.3 per cent it failed to improve and 0.6 per cent died. Among the moderately advanced and the far advanced cases the results were not nearly so good, the proportion of apparently arrested cases falling to 4.1 per cent and 0.5 per cent respectively, the unimproved increasing to 17.6 per cent and 29.7 per cent, and the deaths to 4.1 per cent and 33.0 per cent. This is well illustrated in Table I which is drawn up from the Prudential Chart previously referred to.

### When Prognosis Is Good

On the basis of Table I it will be seen that the prospect of arrest of disease is very good among the incipient cases (1:3), but is very poor in the moderately advanced (1:24), and is almost nil in the far advanced cases (1:200); while death occurs only rarely in the incipient cases (1:166), occurs more frequently in the moderately advanced (1:24), and is very likely among the far advanced (1:3).

A study of this table also reveals a point which is worth while mentioning as it illustrates how inadequate are our present methods in the early detection of the disease. It will be seen that while only 15,807 incipient cases are reported, there are 28,138 moderately advanced, and 25,484 far advanced cases. In other words only about 22.9 per cent of the cases sent to sanatoriums are in the incipient stage, while approximately 40.5 per cent and 36.6 per cent, are already in the moderately advanced and far advanced stages respectively. If our present methods were adequate and effective there should be a much greater proportion of incipient cases being placed under sanatorium treatment than this table suggests as now being the case.

There is another factor which must be considered in a discussion of the early recognition of the disease and that is, that the earlier the discovery of a case in the incipient stage of the disease the shorter is the time usually required to bring the patient to a point where the disease may be considered as being arrested, the less time is lost from work. In the majority of cases this element of time necessary to secure recovery is equally as important as that the man regain or preserve his working capacity, and this again is almost as essential as the preservation of life.

<sup>2</sup> Journal of Outdoor Life, January, 1922, p. 30.

Granting that the importance of early recognition has been demonstrated, the question remains as to what is the most efficient method to pursue in order to secure this early detection of the disease. Several plans have been tried in the past which were based upon the employment of entrance examinations combined with a re-examination of those workers in which either suspicious signs were noted at the entrance examination, or in which suspicious symptoms subsequently developed. The detection of these suspicious features being left to the nurses, foreman, or fellow workers of the individual, or to the physician himself when the man comes under his observation on account of injury, reporting for illness or some similar reason. While this plan possesses certain features which would recommend it to the heads of the plants and those interested in not having the running of the plant interfered with by frequent examinations of the employees, it is too haphazard to be considered as an efficient or comprehensive method from the standpoint of prevention.

While undoubtedly a certain proportion of cases of tuberculosis will be discovered by this method, they will in many instances only be recognized when the disease has become fairly well advanced, when they can no longer be considered as being early cases. When this disease has reached a point where its presence is apparent to the laity, on account of the general symptoms and appearance of the patient, it has usually reached a fairly well advanced stage.

The truth of this statement was very clearly established in a general examination of the 5,706 police and firemen of the City of Philadelphia recently conducted by the Henry Phipps Institute, in which nearly two-thirds, (64.0 per cent), of the cases of tuberculosis discovered had never been previously suspected, even by the individual himself. The proportion of unsuspected cases showing a gradual decrease as the extent of involvement or definiteness of the lesion increased, the proportion of unsuspected cases being very high, (93.1 per cent), among those with early or questionable lesions, and only moderately high, (56.2 per cent), among those with well developed disease.

This survey of the police and firemen was carried out by the Phipps Institute with the object of determining the incidence of defects to be found in a group of this kind, the data obtained to be used as an illus-

tration of the value of health examinations; to furnish us with information as to the best methods to employ, the cost, time required, etc.; and to perfect an organization to conduct such examinations. The purpose of the study was the development of an industrial department which would be prepared to conduct health examinations for the industrial plants in and about Philadelphia, and to furnish them with a diagnostic clinic to which could be referred such cases as the industrial physicians felt required advice from men who had had special training and experience in their several branches of medicine and who had access to special diagnostic facilities.

We have at our command a method for the early detection of tuberculosis which is as efficient and satisfactory as any we can hope to develop in our present state of knowledge. A well organized system of complete physical examination of all applicants for positions, with a careful adjusting of the work to suit the fitness of the man, combined with periodic health examinations of the entire working force affords an efficient means of detecting disease in its earlier stages, provided the intervals between the examinations are not too long. I have been unable to secure any data which will accurately establish just how long this interval should be. Most of the plants employing periodic examinations perform them at intervals varying between one month and three or four years. The very short intervals were employed only when the occupations were extremely hazardous, as in chemical plants. It would seem that they would be most effective in any general plant if conducted annually.

When we refer to these examinations it must be understood that reference is made to a complete, general physical examination, as any examination which would be carried out for the detection of tuberculosis alone would be both inadequate and impracticable. The expense involved would not warrant such studies for the detection of one disease alone, and it is just as important in the prevention of this disease that defects of all kinds be recognized and corrected as it is to discover signs of tuberculosis. The prevention of the development of tuberculous disease depends upon maintaining the general health of the workman at the highest possible level, which would be impossible if defects of various kinds are permitted to pass unrecognized and uncorrected.

While the periodic health examination is an essential if disease is to be detected among workmen at a time when remedial measures promise the best possible results, they must be combined with entrance examinations of all applicants for positions if the prevention of disease is to be really effective. From the standpoint of tuberculosis the entrance examination serves as a means of detecting individuals who are suffering from active disease, cases which should be at rest under treatment and not performing work of any kind if their health and life are to be preserved. These men are also possible sources of infection to the other workmen and should be rejected as a safeguard to their own health and to that of the other workers in the plant.

But the rejection of unfit and dangerous cases is not by any means the most important function of the entrance examination. In the examination of a large number of applicants a certain proportion of them will be found to be below par, possibly suffering from defects which it may be impossible to correct but which will not seriously interfere with the working capacity of the man as long as he performs work for which he is fitted and which will not tend to aggravate his disability. For example, a number of men will be discovered in which evidence may be present which points to some defect of the lungs, signs suggesting pulmonary disease, including those cases, so difficult to evaluate, with signs of slight contraction or fibroid change at one apex or both apices of the lungs. These cases often may be below the normal weight for their height and age. The selection of the kind of work these men may be permitted to perform without the risk of their pulmonary defect becoming an active disease process requires the exercise of the greatest care and judgment on the part of the examining physician. While probably the large majority of these cases may perform work of a proper kind under suitable conditions with perfect safety, they should not be assigned to any position which would expose them to such industrial hazards as dust, dampness, poor ventilation, great variation in temperature, or be allowed to undertake heavy manual labor. The entrance examination is more important as a means of fitting the man to the job than as a barrier to the unfit or dangerous workman.

Any discussion of the function of the entrance examination is incom-

plete without some reference to the classification of occupations in industrial plants, which has recently been receiving some attention, and which, if carefully planned and defined, would materially assist the work of the examining physician. Any classification of occupations must be made with the greatest possible care, with due consideration of the defects most commonly encountered and the effect upon them of every industrial position. While this is sufficiently important to receive the earnest thought and study of every industrial physician, the subject is too involved to discuss in detail in a general paper of this kind.

The phase of this subject which is of most interest and the greatest practical importance to the physician engaged in making industrial examinations is that relating to the diagnosis of tuberculosis. He is most interested in securing information in the direction of aiding him in the determination of what cases should be considered as suffering from tuberculous disease, which cases with signs of pulmonary defects might still be accepted for employment, and what signs should be looked for in the re-examinations as indicating the development of disease. For the physician to judge these cases with any degree of accuracy it is absolutely essential that he be thoroughly familiar with the manifestations of the disease, its varied clinical types, and the physical signs and symptoms which indicate its presence, and, what is equally important, its degree of activity.

Contrary to the very general belief, this does not necessarily mean that every examining physician should be what is generally termed a "tuberculosis expert." It does mean, however, that he must carefully and thoroughly examine every case coming under his observation. More cases of tuberculosis pass unrecognized because of lack of care and thoroughness in the examination than are missed because of inexperience or ignorance on the part of the physician. The examiner must be constantly on the alert for the possible presence of tuberculosis in every case, regardless of his general appearance or state of nourishment, and he must be familiar with the signs and symptoms which suggest its presence. If he does not feel qualified to make a final diagnosis in questionable cases he should arrange to have these cases studied by someone possessing special knowledge, with access to diagnostic measures which the general physician does

not possess, either by sending these cases to the specialist or by having him visit the plant.

The discussion of the physical signs and symptoms is too large a subject to consider here in detail, but reference might be made to a few signs or symptoms which may be obtained with very little effort and would assist in indicating which cases should be most carefully examined for the presence of this disease. In our examination of the police and firemen previously mentioned it was found that the presence of such signs as underweight and low blood pressure may be looked upon as signs of suspicion, and the cases with these signs should receive an examination of chest which is more thorough and exhaustive than it is practicable to give to every case. This must not be taken to mean that the chest of all others may be ignored or examined superficially, but merely that this special group should receive an extra amount of time and study. (This

question has been considered in detail in a previous article of the present writer, which is to appear in the *Journal of Industrial Hygiene*).

### Summary

The industrial phase of the tuberculosis problem may be said to consist of three principal divisions, namely: (1) improvement of plant hygiene; (2) education of the workman in regard to preventive measures and in regard to improved living conditions; (3) the institution of entrance examinations combined with periodic health examination. Preventive efforts directed along these three lines, if intelligently and competently executed, may be relied upon to secure results which will materially reduce the loss of time, efficiency, money, and life for which this disease is responsible in every industrial plant and in every group of workmen, and which would be reflected in an improvement in the general health of the public.

## National Safety Council

THE eleventh annual meeting of the National Safety Council, scheduled to take place in Detroit, August 28 to September 1, 1922, presents many interesting features on its program. One section, devoted to plant publications, is particularly valuable in its suggestions of methods and means as applied to getting the safety message across, and a specific study is promised of the practices of ten representative publications.

Another feature, designed to bring out the functions of employees benefit associations, emphasizes the reduction in claim costs consequent to health supervision, this phase of the subject being presented by Dr. R. S. Quinby, of Watertown, Pa. Another interesting topic on the program of this section has to do with the "Relationship of Disabilities Resulting From Sickness as Compared to Those Resulting From Accident," in connection with which discussion will bring out how best to reduce sickness disability.

Throughout the program are many topics specifically related to the health program in industry, such as eye injuries, dust hazards, noxious gases, industrial poisons, diseases of occupational industrial dentistry, industrial hygiene, the part of the plant surgeon in disease and accident prevention, and the aims and ideals of the plant physician.

The following addresses are scheduled for the Section on Sanitation and Factory Housekeeping:

Miss Tracy Copp, chairman, Women in Industry Section, N. S. C., special agent, Industrial Rehabilitation, Federal Board for Vocational Education, Washington, D. C.

Dr. R. S. Quinby, chairman, Health Service Section, N. S. C., manager, Service Department, Hood Rubber Company, Watertown, Mass.

### Thursday Afternoon

(1) How to Make a Sanitary Survey of an Industrial Plant, by Dr. George M. Price, Joint Board of Sanitary Control, New York City.

(2) Factory Housekeeping from the Standpoint of the Workers' Health, by H. A. Schultz, assistant manager, Bureau of Safety, Sanitation and Welfare, United States Steel Corporation, New York City.

(3) The Problem of Eye Strain in Industrial Occupations, by Dr. Nelson Black, Milwaukee, Wis., and E. Leavenworth Elliott, consulting engineer, Boston, Mass.

(4) Carbon Monoxid Poisoning, by Dr. Yandell Henderson, Yale University, New Haven, Conn.

Of particular interest is the discussion of "The Industrial Surgeon as a Safety Engineer," by Dr. Irving Condit, chief surgeon, General Accident Corporation, Detroit, Mich.

# Gonorrhea and Syphilis in Industry\*

BY WILLIAM F. SNOW, M.D., GENERAL DIRECTOR, AMERICAN SOCIAL HYGIENE ASSOCIATION, NEW YORK CITY.

**B**EFORE the World War the American health officer had established for himself an excellent record in the study of communicable diseases and the elaboration of means of combating and conquering such diseases as yellow fever, typhoid fever, smallpox, and malaria. He had, however, in general, almost entirely ignored venereal diseases, feeling perhaps that they were outside his field. With the war arose an acute sense of the necessity to study gonorrhea and syphilis—prevalent, insidious in their attack, and indirect in their methods of producing morbidity and mortality—so that today there is a reasonable, practical, organized defense against them.

In the beginning the search was for some single key method that would more or less automatically inhibit the spread of venereal diseases and prevent the development of their late disabling manifestations. No such panacea has been found. The equivalent of effective vaccination for smallpox or of the antiphtheritic serum does not exist. It is commonly recognized that the venereal diseases cannot be controlled by any single key measure, but rather by an intelligent, well balanced combination of all measures and factors known by previous tests to have some value.

## Four Major Activities

These consist of four major activities, which are:

*Education.*—To spread adequate and correct information about the venereal diseases.

*Law Enforcement.*—To bring about adequate social-hygiene legislation and law enforcement to reduce prostitution and the resulting venereal diseases.

*Medical Measures.*—To bring about provision of adequate and available facilities for diagnosis and treatment (free treatment when necessary) of all individuals, and to develop more uniform provision of treatment on the part of general hospitals in well correlated in- and out-patient services.

*Recreational Facilities.*—To stimulate community recreation and other activities which tend to improve the general well-being of the community.

By conscientious, persistent application of this program, it may be hoped that a definite reduction of new cases and prevention of serious complications

and sequelae may be brought about.

There is sufficient scientific knowledge about both gonorrhea and syphilis to warrant the planning of lines of attack that closely parallel the usual procedure for other communicable diseases; that is, measures for the discovery, treatment, and control of individuals already infected. Early recognition favors success both in treatment and in prevention. It is essential to keep patients under supervision until treatment has been completed. The elimination of conditions of environment that favor the dissemination of infection by limiting the opportunities of the carrier to spread disease is necessary for the protection of persons not yet infected.

From the point of view of the employer, gonorrhea assumes an interest because of the possible resultant time loss.

The subject of gonorrhea is a matter for consideration by the employer in the planning of the general sanitation of the plant: in the problems of the washroom, the toilet, the disposal of waste, etc. Loss of time may be a factor here if opportunity is not afforded for carrying out treatment as outlined by the physician.

Perhaps, too, time is required for attending a clinic, for the use of injections, or for rest in bed.

The person with acute gonorrhea probably consumes more time in the lavatories of the plant, and in travel to and from them, than other workers—not merely for treatment, but because of urgency or frequency of urination. The elements of mental distress, lack of concentration, loss of interest, etc., may not appear very great in the case of gonorrhea, but the person with epididymitis or a fairly tight stricture is disturbed and distressed many times in a working day. The question of cost of treatment and the danger of falling into the hands of unscrupulous doctors add further to the person's unhappy frame of mind.

Syphilis, from the point of view of the employer, is more important than gonorrhea, because of greater morbidity, greater communicability, and its being a source of greater worry.

Unlike gonorrhea, syphilis is immediately recognized by the layman as a terrible thing, and the first few weeks or months of infection are fraught with anxiety. His mental disturbance

over the disease, its cost, and its possible effects may be a considerable factor toward upsetting his normal relation to his work.

No medical argument is needed to prove the communicability of syphilis, or that syphilis in its active stages with open lesions is a distinct menace to people working in close contact, with common tools or utensils. This, then, should have the employer's consideration.

The morbidity of syphilis manifests itself in numerous ways, and is no doubt felt in plant costs and production rates.

Absenteeism in the case of syphilis may extend over a long period of time. A person with syphilis may have to attend the clinic or the physician's office once a week for a dose of arsphenamin. He may have a slight reaction or disturbance of too little moment to be dignified by the term "arsphenamin reaction," but he is certainly less efficient at work the following day, even though he may not have to stay away from his job. During the period of time that the patient is receiving mercurial injections, or inunctions for that matter, he is uncomfortable to say the least, and he certainly has a constant reminder of what is the matter with him. He may actually suffer considerable pain for twenty-four or forty-eight hours following the injection. Work that calls for either a standing or sitting position may be decidedly distressing and may distract the person's mind from his job to the extent of creating the danger of accident or damage to material.

## A Harvest of Inefficiency

Reduced production may result from such conditions as muscular incoordination during the early stages of developing tabes; the developing ocular manifestations of syphilis; the peculiarities of the developing parietic; the bladder symptoms of an approaching locomotor ataxia; the early cardiovascular symptoms which may exist for a long time before an aneurysm or an angina pectoris is recognized; the bone and nerve involvement which cause a person to be treated for headaches or rheumatism or some other symptom before late syphilis, which is primarily the root of the trouble, is recognized. A latent syphilitic infection may play an im-

\*Read before the Seventh Annual Meeting of the American Association of Industrial Physicians and Surgeons, St. Louis, Mo., May 22-23, 1922.

portant part as a factor in the immediate and late consequences of trauma. In fact, trauma in a syphilitic may determine the site of syphilitic lesions in almost any organ of the body.

While the early stages of syphilis and gonorrhea are important in contributing, through actual time away from work and as a result of mental disturbance, to reduced production, accidents, and damage to property; it is in the late disabling manifestations of syphilis that the employer reaps perhaps the greatest harvest of inefficiency on the part of the syphilitic employee, and sustains the greatest losses. The involvement of the nervous system in syphilis is a matter for serious consideration in the study of accidents.

### Protection to Industry

An accident may mean damage to property, injury to employee, or both. In the case of injury, whether venereal disease contributed toward the accident or not, venereal disease in the injured delays recovery and increases the compensation payment to the injured. It has been shown that, if a syphilitic workman sustains, under certain circumstances, an injury which causes an aneurysm or paresis or any of the possible results of traumatizing syphilitized tissue, he is entitled to compensation, provided it can be proved that injury arose in the course of and through employment. The pre-existence of syphilis does not lighten the responsibility of the employer for compensation for injury, disability, or death, indirectly due to syphilis.

There is hardly a phase of plant management, therefore, that may not be affected by the presence of venereal disease which is unrecognized or, if recognized, is uncared for.

What is industry doing to protect itself? In its consideration of details of plant construction and in promoting physical, mental, and social health among its employees as a means to efficient operation, have not gonorrhea and syphilis a very important place? The means open to the employer for reducing the effects of gonorrhea and syphilis are the means for early recognition of cases of gonorrhea and syphilis and their proper disposition for careful and thorough diagnosis and adequate, conscientious treatment.

Is it not feasible for industry to approach the problem through the physical examination for employment, or, where it exists, through the periodic examination, and, in addition, through the occasional examination after accident or illness? It does not

seem entirely practicable or desirable to attempt to develop a short-cut such as a routine Wassermann for the recognition of syphilis. It is probable that the shortest way to the recognition of gonorrhea and syphilis is to be found in the longer procedure of the ordinary physical examination. The more value there is attached to the examination, the more important becomes the recognition of syphilis. Greater special observation in the routine examination for certain occupations facilitates the recognition of syphilis if the examiner is keyed up to a recognition of the peculiar conditions indicative of the syphilitic background. It is feasible for the clever medical man to include a few high lights or signals in his ordinary method of examining. The observation of these signals becomes incidental and requires but a few moments more in the examiner's regular procedure.

The alert examiner watches the patient's walk and evaluates mental capacity and defective hearing during the preliminary period of the examination. The ataxic gait, mental slowness, defective hearing, voice defects, irregular or unequal pupils, pupils that react abnormally to light and accommodation, large lymph glands, mouth conditions, scars not obviously due to injury, cardiovascular disturbances, and altered reflexes are some of the more common generally recognized high lights. Easily discernible symptoms when found alone or in combination make further examination for the detection of syphilis necessary.

### Remedy Is Social

It is not recommended that any special emphasis be placed upon the venereal diseases in the physical examination of the employee, any more than it is desired that the venereal diseases be overemphasized in relation to the general problems of public health and communicable disease control. The important point, the thought to be emphasized, is that no health program is adequate that omits them, and no physical examination is complete that ignores them.

Should the medical department of an industrial organization provide for the diagnosis and treatment of gonorrhea and syphilis? It is doubtful whether this is either desirable or economical within the plant itself, unless there are no other facilities available or possible of development. Moreover, the employees themselves would probably place obstacles in the way of the success of such a project. The

question is a social rather than an industrial one, and the community should undertake the provision of treatment facilities. If industry provides facilities for making diagnosis of venereal diseases, the cost of treatment should be the concern of the individual or of the community.

It is reasonable, however, to expect that industry should be interested in the betterment of community medical service and that it should cooperate with local authorities in the establishment of diagnostic and treatment facilities. For industrial organizations that are largely the community it may even be a profitable investment to finance entirely the community's attack upon gonorrhea and syphilis.

### Cooperate with Community

The industrial physician has probably as many avenues of approach, open or that can be developed, to the health department, to the clinic, to the specialist, and to the general practitioner as any one medical person. He comes in contact directly or indirectly with a greater proportion of the population than any other trained medical individual in the community. His possibilities as a teacher or a developer of post-graduate medical work are very definite. He must be a booster of better work in the medical and allied professions, lest he have no place for proper reference for and care of the person who comes under his official notice. He has an opportunity to serve his employer, and is justified in taking that employer's time, by planning for post-graduate work for the community physicians through the county medical society and other local agencies, such as the hospital and the dispensary. It is quite possible for very interesting, instructive, and practical post-graduate teaching to be done with little effort and large returns. A recent experiment of the Medical Society of the County of Kings, of Brooklyn, N. Y., in having a practical course of weekly meetings devoted to simple office procedures, has demonstrated what a county society can do and how appreciative the profession is. Standing-room-only signs have been out since the first meeting. Such activities need initiation and guidance. The industrial physician is accustomed to orderly thinking and planning. He probably has the time and certainly the opportunity. Let him do something similar for his neighbor and ally, the local doctor. The return on the investment will be measurable in increased community health and in the advancement of industry's own welfare.

# Industrial Accidents and Their Prevention

By A. WIESE HAMMER, M.D., SURGEON TO THE PENNSYLVANIA RAILROAD, PHILADELPHIA, PA.

THE subject of industrial accidents is an important one and in recent years many volumes have been written, covering a variety of topics relating to accident prevention, yet, notwithstanding the marked attention focused upon this matter, the results attained have not been particularly encouraging. The title of this article, as simple as it appears, involves some of the complexities which arise under the heading of political economy, sociology, law, and surgery.

Industrial accidents may be classified as those due to physical conditions found in the place of employment; those due to certain physical or mental defects found in the individuals comprising the working force; those due to fires, explosions, and other disasters.

Methods of prevention include protection by means of safety devices, a study of the physical and mental condition of the employees, the removal of a workman from duties where there may exist some hazard peculiar to the person in question, and protection against disaster, as by means of fire escapes in the event of fire. For the best solution of the problems in such situations as these suggested, the places of employment must be carefully inspected for possibility of accidents, this inspection calling for the united study of engineers, management, employees and medical staff.

These few introductory words bring us face to face with the consideration of the burden of industrial accidents and the compensation allowed to workman for losses sustained in the pursuit of their daily work. For the equitable adjustment of such losses, the Federal Government and many of the state legislatures have special committees appointed to investigate the causes of such accidents and to devise a legal procedure whereby those suffering injuries, not the result of their own negligence, may be properly compensated.

It was estimated by the late John Mitchell, vice-president of the American Federation of Labor, that in this country at least 35,000 lives are sacrificed each year as a result of industrial accidents. Each new invention exacts its toll in killed and injured workmen. Each new speeding up of the mechanisms of industrial life, each increase in the number and size

*The wisdom of industries employing trained surgeons is emphasized by State Compensation Boards as a conserving agency in the realm of economics.*

*Not only are the injured given expert treatment directly following their accident and are enabled to return to work sooner, thus saving the company money, but compensation claims are correspondingly reduced.*

of mighty engines, brings with it fresh human sacrifices. Each year the locomotive augments the number of its victims; in each year is lengthened the roll of men who enter the dark and dampness of mines, never to return. Many thousands lose their lives in factories, mills, and mines. Many die from poisonous fumes generated in industrial processes or from poisonous substances from constant contact of the hand and lips. Many of the fatalities attendant upon the tremendous industrial movements of a great nation are well within the bounds of human control and many fatal accidents may be avoided through the exercise of proper care and restraint.

The number of industrial accidents in the United States, as compared with other countries in proportion to the number employed, is as three to one. The number of deaths directly due to industrial pursuits is enormous, but as the late John Mitchell asserted, such accidents and deaths cause no shock to society, for what appears to be an "occasional" maiming or killing of an employee, is not regarded as dramatic or startling. Public apathy in this matter will yield only to an understanding of the gravity of the aggregate loss of life and efficiency.

Were it not for this indifference, more precautions would be taken to protect the lives and guard the health of these toilers; and where the fault lay not with the workmen but through the negligence of his employer, more adequate compensation for those who fall victims to the hazard of industrial occupations would be provided for. A case in point is the fact that, though the dangers incident to a miner's life are the same the world over, the number of fatalities abroad is 1.45

per 1,000 men employed or 14 per every 10,000; in this country, the proportion is 35 per 10,000, our excess rate being chargeable to the inadequate laws and imperfect enforcement of existing laws.

It is interesting to note in this connection the importance attached to the employment of skilled surgeons, a measure advocated by compensation authorities as a conserving agency in the realm of economics.

In 1911, the first Employee's Compensation Act was passed. Since then thirty-seven states have adopted similar laws. The correct interpretation of these laws in many of the states is so binding, and the provisions so drastic, that the man who would employ defectives would be foolhardy indeed. Thus, a one-eyed man who seeks a dangerous employment and is accepted, would have a claim for total disability should an accident destroying the other eye occur in the course of his occupation. Contingencies like this have caused many industrial concerns to establish a system of medical inspection of employees, especially of applicants for positions, in order to minimize the number of compensable cases.

State Compensation Boards are constantly emphasizing to industrial plants the wisdom of engaging the services of the best surgeons. This advice is based upon the assumption that the quicker the recoveries and the better the functional results obtained, so will there be a decrease in the ultimate expense. In support of this statement the words of Chas. F. Andrus, chairman of the Illinois Industrial Commission, appear pertinent:

The medical directors of the Commission can do much to assist in encouraging employers to procure the proper kind of medical treatment. They can be shown that there is nothing more costly than cheap medical work. The experience of one large firm in Chicago with their medical department illustrates it. This company was paying their medical head seventy-five dollars a month and imagined they were saving money. They concluded to change their system and put a trained surgeon in charge. The first year the medical expense increased 800 per cent. In the preceding year the Company had thirty-one law suits. In the first year of the new system, they had one suit and the claim department saved thirty thousand dollars. This was accomplished in several ways. Regardless of ex-

pense, the men would get the proper kind of medical treatment and they were able to return to work sooner. The physician told the workmen the exact truth about their conditions and did not act as a sounding board for the claim agent. The consequences were the men had confidence in the surgeon in charge and ambulance chasers did not succeed in stirring up trouble. They were ready to make a settlement on what the physician told them as they knew he was telling the truth . . . thus, it may be readily seen that cheap medical treatment does not pay.

In this connection, the Industrial Accident Commission of California, in its 1918 report, states:

The company with the closest personal scrutiny by its medical chief and the highest type of medical men to do the work, seems to obtain the cheapest and the best medical results. . . . Frequently the course of a surgical case is determined by the first treatments. This leads to the thought that to obtain the best surgical results in accident cases, the injured must fall into the hands of a competent surgeon without delay. Furthermore, it leads to the thought that unless a doctor is qualified to do major surgery he should not attempt to handle a major surgical case, except in emergency, and if he is not able to handle major surgery or to perform major surgical operations, he is ill equipped to make surgical diagnosis or even to recognize major surgical conditions. The minor surgical case frequently develops into a major case. The less skillful the surgeon, the more frequently this happens.

As in all questions where legal interpretation is a *sine qua non*, the drafting of special legislation which appears to the logical mind as reasonable and effective, often receives a sudden setback when the technicalities of jurisprudence are applied to the legislation in question.

This has been pointed out by James Bronson Reynolds, assistant district attorney of New York. The Workmen's Compensation Act of his state provides that employers in certain extra hazardous occupations shall be required to provide compensation to workmen in case of all accidents, unless the responsibility of the workmen for serious negligence is apparent. The bill was carefully drafted and well considered before it was subsequently passed by the legislature. It was well received by employer and employee, and was indorsed by labor organizations as bringing no hardship upon any one and being equally fair to both sides. Yet the Court of Appeals, by unanimous vote decided that the bill was unconstitutional on the argument that such a measure is contrary to the old common law of past

centuries. Reynolds' sharply criticises this antiquated law in its application to present day needs and conditions, and asserts:

Without attempting to pass judgment on the wisdom or the unwisdom of the particular law in question, I do believe that the time has come when we must insist that we shall be free, within certain reasonable limits to pass whatever laws as may seem to us to be just and right, that are manifestly for the welfare of our people of our time. If our courts refuse to recognize the justice of this determination, and declare that the constitution of our states, drafted to secure and maintain the liberty of our citizens, make impossible such social legislation for the promotion of well-being and social progress, then the sooner our constitutions are amended, the better.

This same authority believes that the compensation acts of the different states constitute a valuable agency for the prevention of accidents. But prevention would be better served by workmen's compensation laws if the public, the employer, and the employee—the three parties in interest—each assumed an equal share of responsibility. Under any compensation law all these will bear their burden, but the benefits of compensation will be hampered because the distribution of unassigned burdens is not equitable. If the respective responsibilities are determined fairly and imposed directly, the stimulus to replace compensation by prevention will surely become greater. The public, to reduce its share of the burden will pass more rigid laws to prevent accidents, and be impelled toward proper enforcement; employers will be more prone to install accident-preventing machinery, and the workmen themselves will be more careful and will insist on greater care from their fellows to minimize the likelihood of accident.

The attention of all concerned needs to be directed toward the inadequacy of some of our present laws and the difficulty of framing more beneficent laws that will stand up under the scrutiny of the judicial mind. In many respects the injustice of the present system is all too apparent, but in some states at least constitutional amendment is in order before we can hope for more effective laws. For ten years past studies on the subject of accident prevention were crowding the shelves of private and public libraries. The subject—most important alike to the laborer and to his employer—is ripe for effective mutual action.

In this connection, it is of no little interest to regard the charter by

which Congress incorporated the American Red Cross and defined its duties. In that beneficent document, mark these words: ". . . And to continue and carry on a national relief in time of peace and apply the same in mitigating sufferings caused by pestilence, famine, fire, floods and other great calamities. . . . And to devise and carry on measures for preventing the same."

In the First Aid Textbook for Red Cross Workers, Surgeon-General O'Reilly offers the following prefatory thought: "Notwithstanding the many excellent works already in existence on first-aid instruction, none of the writers, so far as I know, has given much thought to teaching the *prevention* of accidents. While this subject is necessarily treated rather briefly here, at least enough is said to call attention to the importance of prevention, as contrasted with cure, and for this reason it seems to me peculiarly appropriate that this book should have the endorsement of the Red Cross, as the beneficent mission of that Society like that of the good physician in treating of diseases, should be to go deeply into causes, and their responsibility for the physical sufferings of humanity, rather than to resort solely to palliative measures."

The industrial edition of this valuable manual issues the following "nevers" and "don'ts" for railroad employees, for the public when approaching railroads, etc. For the railroad employees, there is proposed both theoretical and practical instruction in railroading, the use of safety appliances, common care on the part of employees, etc. For the passengers there are warnings: "Never cross a railway at a grade crossing before making sure that no trains are approaching." "Never jump on or off a car in motion." "Never forget that carelessness on your part in regard to these precautions not only endangers your life but the welfare and happiness of those most dear to you."

These statements may appear like truisms, but so great a number of injuries result from violations of these simple rules—these precautions believed to be innate in the mind of every sane man and woman—that the Red Cross had sixty thousand of these precautionary measures printed on posters and distributed to railroads.

At frequent intervals, papers and essays, communications and printed admonitions are being issued through factory inspectors, railroad companies, through the workmen's compensation

1. Annals of the American Academy of Political and Social Science, xxxviii, No. 1.

bureaus of the department of labor and industry, urging safer devices on the part of employers and greater care and less negligence on the part of workmen, in order to minimize the number of accidents.

Crystal Eastman, secretary of the New York Commission on Employers' Liability and Causes of Industrial Accidents, asserts that the first essential in accident prevention is complete and accurate information about accidents that are happening, not how many die, but how many are killed in proportion to the number employed. And especially important is it to find out not so much how it happened, but what time of the day it happened and how long the injured man had been working, his regularly working hours, etc.; the idea being to collect those salient facts that will enable one to analyze these accidents with a view to prevention.

Mr. Eastman, emphasizing the paucity of exact information, cites the fact that the Minnesota Labor Department secures its first notice of almost every accident through its newspaper clipping service. If, in the course of a few days no report is received from the employer, the clipping is sent to him with a notice of the law's requirement and the blank form which is to be filled in with a full account of the accident. As a result of figures acquired in this way, the following statistics are given: The largest number of cases of death and accidents were in mining, railroading and lumbering: contracting work, 37 killed, 717 injured; agriculture, 12 killed, 51 injured; public utilities corporations, 19 injured, etc.

The second essential for accident prevention is means for enforcing the accident prevention laws commensurate in equipment and power with the importance of its duty. It is a moot question whether these measures should be delegated to a special department, or combined with the factory inspection bureau of the labor department, along with the enforcement of child labor laws, and general inspection of sanitary conditions. In any event it would reduce the appalling number of preventable accidents to make rules of safety in the different trades, rules which shall have the force of statutes. The commissioner should be given, expressly by statute, summary power, in case his orders are not complied with, to call on the police and close up a factory, prohibit all operation of it until his orders in regard to safety are carried out; this summary power to be exercised, of course, only after due notice.

## Recent Compensation Decisions

BY DOROTHY KETCHAM, DIRECTOR, SOCIAL SERVICE, UNIVERSITY HOSPITAL, ANN ARBOR, MICH.

THE Court of Errors and Appeals of New Jersey, February 9, 1922, decided that, where an employee fainted following an inoculation and fractured his skull, the injury was compensable as one "arising out of and in the course of employment."

It seems that during the influenza epidemic of 1918, the Company, in an effort to check the spread of the disease, administered through its company physician vaccine to those employees who were willing to take it and to their families. On October 23, 1918 this employee, Harry Freedman was inoculated at the plant with the other men of his department. On returning to his desk as a result of the inoculation he fainted and fell to the floor fracturing his skull. The next day he died. The Court affirmed the award that the injury was the result of an accident arising out of and in the cause of employment, without opinion and unanimously.—*Freedman v. Spicer Mfg. Corporation*, 116 A. 427.

LEAD poisoning is not compensable as an industrial accident according to the Supreme Court of Oregon in its decision of April 18, 1922. This objection may be raised in the Supreme Court.

The employee, it seems, was engaged in building cars for the Pacific Car and Foundry Company where he was occupied for seven weeks in upholstering. He states that he put nails in his mouth and that a severe case of lead poisoning ensued, resulting in obstruction of the bowels.

The Commission at first disallowed the claim, but later reconsidered it, made an adjustment, and finally specified the allowance. The question of jurisdiction will not be here discussed, the question of compensability of the disease being of interest. The Oregon law covers "personal injury by accident arising out of and in the cause of his employment and resulting in his injury." In the opinion of the court, "the basic fact is without dispute that what happened was a disease contracted over a space of about seven weeks, in the ordinary conduct of the occupation in which the claimant was engaged. In other words, this is a case of occupational disease. From the precedents cited, the analogy is plain that such an objec-

tion may be raised at any stage in the Supreme Court.

The decision of the Circuit Court was reversed. The term accident was defined as including "suddenness or unexpectedness." "It does not allude to the steady and imperceptible advance of disease in the human system. It would be competent, of course, for the Legislature, in the exercise of its police power and the usual care for those who toil to provide compensation for occupational diseases, but it has not done so and we cannot read into the statute compensation for ailments which do not come within the scope of an accident caused by violent or external means."—*Invanicki v. State Industrial Accident Commission of Oregon*, 205 Pac. 990.

COMPENSATION may be awarded for an injury although there is a pre-existing disease if that disease is accelerated or aggravated by an injury but it will not be awarded if the disability is due solely to a pre-existing disease and would have arisen regardless of the injury according to the Supreme Court of Illinois, April 19, 1922.

It seems that Kenney, the employee, was injured by a fall of coal in Keller's mine. Award was given "for the reason that the injuries sustained caused the permanent and complete loss of the sight of his right eye and the permanent loss of one-third of the sight of his left eye." The award was affirmed by the Commission and the Circuit Court. It seems that about three weeks after the man's return to work, he began again having trouble with his eyes. An attendant physician made a diagnosis of tabes dorsalis and started treatment for syphilis.

The story of the injury is confused and unreasonable. "The facts that the defendant in error returned to work nine days after the injury and worked steadily as long as the mine worked, that the defect in his sight did not appear for several weeks after the injury, and that there is no evidence connecting the disability with the injury, are not consistent with the decision of the Industrial Commission. The award must be set aside, the judgment was reversed, and the cause remanded with directions to set aside the award of the Commission for further hearing."—*Keller v. Industrial Commission*, 135 N.E. 98.

## Dietetics for Workmen

THE "personal equation" is everywhere referred to in these latter days as an unknown quantity, as if it were intangible, variable, unpredictable, and beyond control. It is incriminated with being the cause of the residue of accidents held to be unpreventable, and accounting for lowered output and for failure in general. It remained for Amar<sup>1</sup> to prove the thesis that the personal equation is a constant, not a variable, that it is fixed within certain limits for each individual and subject to accurate measurement inasmuch as it is the sum total of reaction times, of excitations and reposes, and that its expression through the rhythms of physiologic impulses is not modified except by fatigue. It becomes a puzzlingly uncertain factor in management only when the fundamental requirements of the human motor are not understood and properly provided for. Especially are the fortuitous accidents due to end of the day and end of the week fatigue subject to remedy through control of food periods and the proper intervals of rest.

The power machine that runs under continuous pressure must be fed by a continuous stream of energy. The human motor, through a system of combustion called nutrition, is able to assimilate and reserve food materials in a manner which permits its slow oxidation in the tissues and its utilization as the source of all the energies of the being. If such reserve is not possible through the food obtained, then the substance is rejected and is useless as nourishment.

The body of man contains about 60 per cent of water and loses about two or three kilograms of water per day in repose. Lack of water may be a grave danger and lead to respiratory, cardiac, and often nervous trouble. Besides the aliments obtained through carbohydrates, fats, and proteids, the organism needs "mineral salts," especially sodium chlorid. The latter regulates the concentration of the organic liquids, provides the gastric juice with its acid property, and aids the water to preserve the elastic state of the tissues so necessary in the transformation of its energies. The calcium salts consolidate the growth of the skeleton during its period of growth, and par-

ticipate in the physico-chemical phenomena of life. The insufficiency or absence of these (mineral inanition) produces grave illness which affects the nervous system. Other minerals, such as iron manganese and zinc, seem to serve as cellular "excitants" and have a necessary part in the life of the microorganism.

### The Maintenance Ration

The maintenance ration is not the same for everybody. It depends upon the total bulk of the body—which varies with age and sex—also on the external environment and on the state of repose or activity. Hence the importance of relating the dietary of the workmen to the specific requirements placed upon him. It has been definitely proved that energy is best derived from a mixed ration of fats, proteids, and carbohydrates and that the body is never indifferent to the relative proportions of the sources of this energy. The food must contain a proportion of one gram of proteid to one kilogram of body weight and enough of carbohydrates to suffice for the muscular work required. For the regulation of the temperature, the fight against cold, the nature of the combustible needs to be different.

When the organism suffers from inanition, the tissues are attacked in the order of their importance, the motor organs reacting less quickly than those of nutrition. The magnitude of effort produced depends largely on the nature of the food consumed. Men addicted to working at high speed do not develop muscularly, but have slim, rather thin bodies. They have generally less appetite than other men. It is noted by Amar that by so simple a device as regulating the hours of feeding the strength may be maintained at its peak at the time when the demand upon it is greatest. Not only must the quantity of food be maintained ample but the proper balance of rations to keep the worker at his best performance and—what is really the same thing—that without prejudice to his physical health and general welfare. In this connection it is significant that all inquiries which have been made into the dietaries of the working classes have, with few exceptions, shown that it is faulty and general not well chosen for the physiological purpose; further, it is often insufficient. Workmen are, as a rule, smaller than the general population: laborers in workshops

and mills are smaller than those who live in the open air; the poor are smaller than the rich in the same country and town. Amar's report is based on French observations, but the same general conclusion was reached by American investigators in a study of 14,000 persons in the northern states. The foods chosen by this large group of workers giving bulk rather than nourishment was excessive. The *Institut Solvay* studied 1,250 working class homes in Belgium. Various occupations were represented, most of them involving heavy manual labor, but their daily consumption of proteids did not average more than 90 grams, being highest in the heaviest trades and the best paid occupations, and least in the lightest and worst paid occupations.

It is unreasonable to suppose that a balanced ration will be chosen by intuition or by preferences of taste of the individuals most concerned. Nor is the remedy for inadequate dietaries to be found by community kitchens, such have been advocated under certain European conditions. Difficulties in the way of keeping up the peak condition are obviated when adequate employees' food service is possible in industry, but the real remedy lies in the direction of public health education and is to be found (1) in instructing the masses as to what to eat and why; (2) in maintaining nutritional observations on a large scale to enlarge our scope of knowledge of the whole subject, and especially to direct economics studies toward the production of sufficiently cheap supplies to make them available to all classes. The most important phase of the work is the education of the masses along nutritional lines, for inanition due to insufficient food and the obscure disorders due to badly balanced rations are by no means confined to the great army of the poor.

The 100-acre tract of land, formerly occupied by Camp Beauregard, north of Alexandria, has been purchased by the State of Louisiana for the purpose of establishing a colony for mentally subnormal persons. Provision will be made for about 2,000 persons. The main group of buildings will consist of dormitory units, an assembly hall, service buildings, shops, and an administrative building in which there will be a gymnasium. Truck and dairy farms will be established. There will be a competent staff of medical officers, psychologists, and social service workers.

1. Jules Amar: *The Human Motor*, E. P. Dutton & Co., New York, 1920. This work reports all the important investigations on the laws of energetics as applying to the human machine and is the basis of the summary contained in this article.

*The Health Problems of Schools and Colleges, Hotels, Summer Camps, Children's Homes and Homes for Dependents*

## Citizens' Military Training Camps

BY GEORGE F. JAMES, SECRETARY, MILITARY TRAINING CAMPS ASSOCIATION, CENTRAL DEPARTMENT, CHICAGO, ILL.

**H**EALTH, efficiency, and good citizenship is the slogan of the Citizens' Military Training Camps which were initiated last year by the Government under the direction of the War Department at the suggestion of the Military Training Camps Association of the United States. This organization is the outgrowth of the pre-war voluntary camps held at Plattsburg and other points, which led to the training of nearly one hundred thousand commissioned officers for the National Army.

The first citizens' camps were held last year throughout the nine corps areas. Congress provided room for ten thousand young men while applications numbered nearly fifty thousand. On account of the exceptional success of this new movement for national health, the camps this year have been increased in number to twenty-five and room is provided for thirty thousand men.

These camps are located at advantageous sites, many of them at famous training centers for the National Army in 1917. Each army corps area has from one to four of the Citizens' Camps so distributed that there is a minimum of transportation necessary for each man enrolled. This voluntary training aims at preparing young men through a three year series, the Red, the White, and the Blue course, for commissions in the Organized Reserve or the National Guard. Every branch of the service is represented, and candidates may express their preference for infantry, cavalry, artillery, engineer, signal corps or air service units. The cavalry and the Signal Corps seem to be the most popular. In radio development a complete course of instruction is offered.

The camp training is without cost and free of all military obligation. The Government pays all expenses, including transportation, uniforms, subsistence, quarters, and equipment. Army surgeons look after the physical health, army chaplains conduct religious exercises, and army hostesses promote the social life of the camps. The only requirement for admission is good health and character; the age limits are 17 to 25.

Military drill is the main feature of the morning program; the afternoons are given to all kinds of out-door games, and the evening hours are devoted to moving picture shows, amateur and professional dramatic and musical entertainments, to in-door games and dances. There are ample facilities in each camp for libraries, reading and writing rooms, and for the entertainment of friends and

relatives. Picked troops of the regular establishment give demonstrations of every branch of the service; boxing, fencing, swimming, baseball, handball, and tennis are universal sports.

The larger training centers are at Camp Devens, Mass., Plattsburg Barracks, N. Y., Camp Meade, Md., Camp McClellan, Ala., Camp Knox, Ky., Camp Custer, Mich., Fort Snelling, Minn., Fort Des Moines, Iowa, Jefferson Barracks, Mo., Camp Travis, Texas, Fort Logan, Colo., Fort Douglas, Utah, Camp Lewis, Wash., and the Presidio, San Francisco. The smaller camps are located in different sections for the purposes of coast artillery, cavalry and air service.

The training camps are merely the beginning of a great national movement for national health, the upbuilding of American youth physically,

Thirty thousand young men between the ages of 17 and 25 are receiving summer training in twenty-five army camps in the United States.

The signal corps is one of the most popular branches of the service to the summer rookie. A complete course in radio is offered in connection with this course.

mentally, and morally, making them good citizens in time of peace and capable defenders of their country in time of need. Last year ten thousand men were trained; this year thirty thousand will attend the camps; next year it is confidently expected that the number will be doubled. That within a short time one hundred thousand men can be trained every summer is the earnest hope of President Harding. The Governors of all the United States are enthusiastically supporting this new policy which has received the

unqualified endorsement of the pulpit and the press. The Military Training Camps Association first proposed this type of training and is consistently supporting it through the work of its National Officers and its nation-wide membership.

A month out of doors, with no expense, in favored surroundings and an ideal camp program is something which appeals to all red-blooded youth and promises to be a potent factor for health, efficiency, and good citizenship.

## Good Health Week

THE week of October 23 to 30 has been announced as "Health Week," by certain well known industrial groups as a period most favorable for a national appeal to the public to interest itself in a wide range of subjects having to do with hygiene and sanitation, in their direct relationships to individual and community health.

Every week in the year should be a good health week, and would be if it were the habit of the individual mind to focus on essentials to the exclusion of distracting details, or if it were possible for the average person to determine precisely what such essentials are. But apathy so characterizes the average person that, in matters of hygiene and sanitation, for instance, government by experts seems to be the only solution until an enlightened public opinion can be secured through a wider publicity on the physiological and engineering problems involved and on the role of

the individual in forwarding a general health program.

The educative function of committees in charge of "weeks" of one kind and another becomes highly important, therefore, in arousing general cooperation and in revising notions of hygiene to accord with the newer findings in the field of research. In the matter of ventilation, for instance, "Pure air," as a popular slogan is taken to mean, in the home, open windows; and in public places perhaps an atmosphere washed free of certain impurities and low in CO<sub>2</sub> content. In point of fact, the physics of the air is one thing, and its chemistry another, and the old rule laid down by sanitarians that the percentage of CO<sub>2</sub> may be taken to indicate the adaptability of the air for respiration purposes must give way to other considerations. Extreme humidity with stagnation of air is a greater source of poisoning than carbonic acid. Carbonic acid is a bogey;

humidity and temperature control are vital. Respiratory efficiency, so closely allied to physical fitness, is bound up with such regulation of atmospheric conditions as will maintain physiologically normal reaction and oxygen pressure in each of the various organs.

Aside from respiratory demands, there must be assured the stimulus of a constant flow of fresh air, for stagnation of air adds the toxic products of an inactive skin to the discomforts of oxygen want. Even in the Tropics one may work and live in relative bodily comfort if there is free circulation of air. Health, comfort, efficiency, depend upon "preserving constant the conditions of life in the internal environment," that is, the blood. Lower the oxygen content of the blood; load it with toxic products; burden the temperature regulating mechanisms of the body with the task of overcoming the excessive heat and humidity of stagnant air, and both body and mind deteriorate.

Physiological tests, therefore, constitute the basis of all the newer tenets of ventilation experiment. Much value has emanated from the investigations of the British Medical Research Council. Our own governmental departments have contributed many important studies, and many practical suggestions have come from industrial research, such as the preliminary problems connected with the new Hudson automobile tunnel.

If all the results of this research, industrial and medical, are soon to become common property, effectual in improving the living conditions of the people, the message must be popularly stated and widely disseminated. "Health Week" gives research workers the opportunity to tell their story and, incidentally, the people are enabled to find out, not merely what particular problems of hygiene and sanitation have been the immediate subjects of study, but how and where they may find expert help in modifying unfavorable conditions in their own immediate environment.

The matter is not wholly one of atmospheric environment, however, and if physiological mechanisms are not to be hampered by unhygienic conditions, a rational program of personal hygiene must supplement the suggestions by sanitary experts on what are really engineering problems. The athlete, maintained in hard condition by conformance to an exacting régime, shows plainly enough that consistent management will achieve physical fitness. General interest in

personal hygiene is stimulated by competitive games, by gymnasiums, by recreation and health centers, and by the trade in pushing devices designed to facilitate hygienic practice. Far reaching in effect are the enterprises recently reported in the NATION'S HEALTH covering pools for industrial workers in Birmingham, the new public baths in Chicago, Johnstown, Pa., the Baltimore public laundries, and the palatial four-story bath projected for Harlem. The charity that provided facilities for rejuvenation, both of person and of linen, during the unemployment crisis of the past winter was in a high degree intelligent, for the individual rates himself largely in accordance with external signs of refinement and is by the unthinking multitude necessarily accepted on the basis of outward appearance.

Health and personal hygiene cannot be divorced. Even closer is the relationship between health and the food intake, though it is only recently that effective application has been made of the idea of training the appetite, of applying biological tests to nutrition, of specific feeding to pro-

mote growth, to increase endurance, to adapt the climatic or working conditions, to meet the requirements of age, or to correct bodily disorders.

Domestic science courses now include much that is vital in this connection. Intelligent method in budget making is being inculcated in social work, and much that is informative is finally being voiced by the daily press and in other popular channels. Such information, however, is unsystematic, incomplete, and often misleading. Health Week may be expected to favor the collection of all pertinent facts and to drive home their lesson through the intensive interest so that the health implications of every day life may be better understood and promote better hygienic practices everywhere; for, when all is said, intelligent opinion is gauged by the fund of available knowledge. In former days specific information on the essentials of hygiene has been regarded as esoteric knowledge, the special possession of the initiated. It now becomes the right of a public alive to its own problems, and interesting itself in their proper solution.

## Out-door Schools Foe of Phthisis

"IN the outdoor school is found one of the cheapest, simplest, and most efficient remedies for the care and prevention of tuberculosis among children," is the statement made by Dr. John B. Hawes, 2nd, in his book "Tuberculosis and the Community" recently published by the firm of Lea & Febiger, Philadelphia.

Since tuberculosis infection takes place in the early years of childhood, and practically every child has become infected by the time he reaches the age of fourteen, the assumption is that the infection has been gained during his school years. Proper medical supervision during these years would be a great aid in the campaign against tuberculosis.

From the financial standpoint alone, such inspection would be practical, Dr. Hawes points out. Statistics show that the State of Illinois spends \$1,187,000 annually in educating children who die of tuberculosis before reaching the twentieth year.

"Open air schools should be considered as an integral part of the public school system and in no way a public charity," says Dr. Hawes. At the present time in most open air schools only children in an anemic or pre-consumptive state are admitted. This is unfortunate, the doctor thinks, for it should be considered just as important to keep the well children strong and healthy by giving them the benefits of fresh air, mid-morning lunches, rest, etc.

There are two types of buildings used for open air schools. One type of open air school consists simply of a room in the main school building either provided with specially constructed windows or with the windows actually taken out so as to admit the maximum of fresh air. The other type is the "shack" construction, a separate building.

Clothing should be according to the seasons. In winter, Eskimo suits, gloves, and boots are essential. While it is necessary that the air be fresh, the temperature should not be less than 40 degrees F. as extreme cold, just as extreme heat, saps the vitality and does harm rather than good.

The mid-morning lunch is especially important in the open air school as the children's breakfast is liable to be inadequate as far as nourishment is concerned. Careful record of the weight of each child should be kept.

Besides teaching the children the fundamentals of disease prevention and how to maintain and preserve health, the open air school should also provide instruction to the parents. In obtaining the cooperation of the parents, the school nurse is an essential factor. By frequent medical examinations, by plenty of fresh air, proper clothing, rest, and adequate nourishment tuberculosis can be discovered and checked during the years when it is attaining a foothold.

The third pamphlet of a series, "The Schools of Your City," entitled "Health and Physical Education" has been published by the Chamber of Commerce of the United States, conditions needing attention, states the pamphlet, are nutrition, teeth, eyesight and hearing. William Mather Lewis, Chief, Education Service, is author of the bulletin.

The weight of each child should be carefully kept.

# Health Conditions in the Cook County Jail\*

BY R. B. PREBLE, M.D., AND JOSEPH L. MILLER, M.D., CHICAGO, ILLINOIS.

THE population of the County Jail is almost exclusively composed of persons accused of a wide range of criminal offenses who are being held to await judicial action on the charges against them; that a large percentage of them will ultimately be released as "not guilty," and that, whether guilty or not, they are in a large proportion of cases kept in confinement for many weeks or even months until their cases are disposed of.

It is proper to say in this connection that medical science has no concern with the question of the guilt or innocence of the people so confined. It proceeds on the assumption that every person held in detention by the public authorities is entitled to healthful living conditions, a periodic examination into his mental and physical state of health, and to adequate medical care. After a careful examination of the conditions prevailing in the Cook County Jail, we have come to the conclusion that the County authorities have conspicuously failed to perform their duty in the above respects.

*Overcrowding.*—It is no part of our duty to fix the responsibility for the serious conditions of overcrowding which have come to prevail in the jail, but the bearing of these conditions on the general health of the inmates cannot be questioned. The foul air resulting from the crowding of three or four men within the confined space of a single, narrow cell, and of hundreds of men into the congested bull pens; the all but complete lack of physical exercise or of recreation for weeks and months at a stretch; the absence of occupation for mind and body and the inevitable contagion resulting from such close contact cannot but result in an almost universal deterioration of vitality and an impairment of physical health even when acute disease fails to develop. It is equally evident that serious impairment of the nervous system and of the mental health of the inmates must result from living under these abnormal conditions of irritability, especially when combined, as they are, with anxiety and uncertainty as to their ultimate fate or even as to the prob-

able length of their confinement. Wholly apart from the fact that these conditions of congestion make a proper sanitation out of the question, there can be no doubt that they produce a mental state on the part of the inmates that is highly deleterious and that may have permanent effects on their health.

## Conditions Affecting Health

*Infectious Conditions.*—Each prisoner upon being received at the jail undergoes what is designated as a physical examination. This is given by the assisting jail physician, who comes to the institution for an hour or so every evening for this purpose. Before his arrival the prisoners received since his last visit have been searched and given a bath. After bathing, however, the prisoner puts on the same clothes, including underclothing, that he had on when entering the jail. There is no adequate provision for fumigating or sterilizing the clothing to destroy vermin or disease-producing germs, and this is, in fact, rarely done. After the examination the prisoner is assigned to a temporary cell in the receiving wing of the jail. Here he remains over night until assigned to permanent quarters. The linen used on the cot is changed only once a week, so it is possible that he may sleep on linen which has been used by five other prisoners. It is unnecessary to comment on the dangers attendant upon such a procedure, both as regards infection and the dissemination of germs.

*Ventilation.*—The present building was intended to accommodate some 570 prisoners. The average number actually confined is approximately nine hundred. The cells contain 380 cubic feet of air space, and these were intended for two prisoners at the most. Now, however, three or four prisoners are placed in almost every cell, allowing thus an individual air space of a little more or less than one hundred cubic feet. Inasmuch as the minimum requirement is five hundred cubic feet per person where there is through-and-through ventilation, the state of the air in one of those cells where there is no through-and-through ventilation can readily be imagined. The air simply enters at the front of the cell. At the back is the steel door which does not contain a ventilator. This door opens onto the

"bull pen." Each prisoner is kept in his cell twenty out of the twenty-four hours, as he is allowed two hours twice a day for exercise.

The cell is provided with a double deck, or, in some cases, with a three-deck bunk. Where more than two or three prisoners are confined in a cell they sleep on a mattress placed on the floor in the cramped space at the side of, or under, the cot. The width of one cell measured was only four feet, eight inches.

This condition is most deplorable and can be entirely corrected only with the construction of a new jail in which due consideration is given to sanitation, and especially to the provision of adequate air space for each prisoner. Conditions in the present institution could be very much improved, however, by putting a ventilator in the steel door at the rear of the cell, which would permit through-and-through ventilation.

The "bull pens" in which the inmates are exercised are, with the exception of one, fairly well ventilated. This "bull pen" has a low ceiling, is dark and most unsatisfactory. When a new jail is constructed, it is very desirable that some plan be devised by which the prisoners may get exercise in the open air, or at least in a room with sunlight and good ventilation.

*Vermin.*—The relation of vermin to disease is only dimly apprehended by the community at large. To medical science, vermin are not only a nuisance and a sign of a low standard of living on the part of those who tolerate them, but a source of infection and of lowered vitality. The verminous home or institution is a disease-breeding place. The prevalence of vermin in the cells and "bull pens" of the County Jail and on the persons, in the clothing and beds of the inmates is, therefore, a condition which has to do with the health of the institution.

With the present arrangement of replacing the prisoner's clothing after his initial bath, a practice which is described elsewhere in this report, it is impossible to prevent lice, bedbugs, and fleas from gaining access to the cells. The arrangement at the present time is that, if the prisoners complain of their cells being infected with vermin, the vermin are destroyed by the use of gasoline torches. No systematic going over of the cells for this

\*The section of the Report to the Chicago Community Trust on medical and health conditions in the Cook County Jail, a part of a general survey of that institution, now in progress.

purpose is carried out, but only on complaint of the inmates. This should be remedied. All cells should be gone over for the destruction of vermin at stated intervals. By the use of a torch only those vermin are destroyed in the walls or on the floor. No attempt is made to destroy those in the bed. The blankets are only washed at infrequent intervals, as a rule not oftener than once in several months and probably a very much longer period of time. As stated elsewhere, clean sheets are distributed only once a week. All of these practices favor the development of vermin in the cells.

At the present time a concession is granted for a barber shop. Fifteen cents is the charge for a shave and thirty-five cents for a hair-cut. Those prisoners without money are denied the opportunity to get a hair-cut or shave, excepting when summoned to appear in court for trial, and this again may be a very important factor in promoting the development and consequent dissemination of vermin.

#### Food Conditions

The relation of health to nutrition and the dependence of the latter on the regular supply of a sufficient, appetizing and well balanced diet are too well known to require special emphasis in this report. It may be said that conditions in the County Jail in this respect are far from satisfactory. Food conditions in the jail were made the subject of special study by Mr. Winthrop D. Lane. Apart from the fact that the diet is so monotonous and unappetizing in character that most of the inmates refuse to eat it and that it is so heavy and unbalanced that it produces an abnormal amount of digestive trouble on the part of those who are forced to depend on it, the features that call especially for medical notice are the absence of fresh vegetables and the almost complete lack of sugar, milk, and butter or butter-substitutes. These are perhaps, in addition to bread, the most essential elements of a balanced and nutritious diet and it is hardly too much to say that a state of health cannot be maintained without them. It is true that such of the prisoners as have money are able to procure these necessities from the jail store and that those who have families or friends able and willing to help them can procure them from the outside; but there are many hundreds of the thousands that pass through the jail in the course of a year who are compelled to depend wholly on the jail diet. We cannot blink the fact that the possession of money and friends may be an ad-

vantage in a jail as well as in the world outside, but we believe that we are warranted in insisting that where the state has placed men in confinement and prevented them from earning their livelihood, it is under the duty of supplying them with a diet which will be adequate to the maintenance of their health and strength. The question of the jail diet is being studied by a Committee of the Chicago Dietetic Association, which will make special recommendations on the subject.

#### Medical Service

*Physician and Staff.*—The medical service of the jail is directed by a jail physician and an assistant physician, who are assisted by two inmates, serving sentences. The chief physician, as required by law, calls at the jail every morning, and the assistant in the evening. Each is expected to spend as much time as may be necessary, but both are busy practitioners and have little time to spare for the most uncongential and least profitable part of their professional work. They have, apparently, not regarded it a part of their duty to give attention to the ventilation or the sanitary conditions of the place. In fact Mr. Lane reports that the chief physician gave him the comforting assurance that "the jail is a health resort."

With nine hundred inmates, frequently changing, the full time service of one or more competent medical men is required, not merely for the purpose of devoting more time to the examination of prisoners on entrance but also to make rounds through the jail, possibly to detect in this manner incipient disease, to make physical examinations as often as required at least of all those who are suspected of having some progressive disease, and to look after the sanitary condition of the hospital as a whole. A man holding such a position should, therefore, not merely be familiar with medical diagnosis, but should also have some training in sanitation.

In addition to this physician, who would be on service all of the time, there should be at regular intervals medical inspection of the jail by a committee of medical men appointed by some such organization as the Chicago Institute of Medicine. They would thus be able to check up and detect any neglect of sanitation or medical care.

*Mental and Physical Examination.*—There is no mental examination of the inmates on their arrival nor subsequently during their confinement. In view of the fact that a large por-

portion of delinquents are feeble-minded and that many of them suffer from insanity or other psychopathic conditions, the neglect of this elementary precaution cannot be justified.

The physical examination of newly received prisoners is conducted in a very perfunctory manner. On a recent occasion forty-two men were examined in thirteen minutes, part of this time being consumed by the examiner in filling out the prisoners' record cards. On the basis of this brief examination, however, the examiner filled out each man's card for scabies, syphilis, gonorrhoea, tuberculosis, condition of the heart, condition of the lungs, and general physical conditions. It is apparent that an examination of this character is practically valueless except for the detection of very evident lesions. No provision is made for examination of urine or sputum, and no Wassermann tests are made on any of the prisoners in the institution, although some of these prisoners are confined there for many months. In such a superficial examination only advanced tuberculosis could be detected. No doubt many cases of active pulmonary tuberculosis are placed in cells with healthy prisoners and the danger of contagion is very great. Not only may an infected inmate thus unnecessarily expose other prisoners, but in the poorly ventilated and damp cells and with the inadequate food provided, the disease within a few weeks may reach an incurable stage. In such an examination early scarlet fever or measles might also be overlooked, and such a highly contagious disease as itch. Even if the patient were found to have tuberculosis, no provisions are available for proper isolation or confinement in a cell or room properly lighted and ventilated. There is no provision made for the proper disinfection of the cells, so the possibility of an infection like tuberculosis being carried in this manner is certainly very great.

#### Hospital Care

Prisoners with minor complaints are given pills or powders by a prisoner assigned to the dispensary. In the selection of a prisoner for this position, trustworthiness, rather than any special knowledge of pharmacy, is the necessary qualification. Inasmuch as such prisoners serve short sentences, the personnel will be frequently changed. A permanent position should be established and a person selected to fill it who at least has some knowledge of pharmacy.

Serious cases of illness are treated

by the prison physician in the hospital. The jail at present has two hospital wards. These are known as Hospital A and Hospital B. Hospital A is located on the top floor. It is a large, suitably lighted, airy room with toilet facilities, which could accommodate, without unnecessary crowding, twelve patients. On the day of our visit there was just one patient in this room, a prisoner ill with pneumonia.

Hospital B is on the ground floor. It is a room approximately forty by twelve feet, and was constructed by walling off a part of a wide corridor, or what was no doubt intended for a "bull pen." The walls are simply heavy wire netting with canvas on the inside at one end. The ceiling is low. There is no outside light. The room is damp, uncomfortable and most insanitary. It has no proper toilet facilities. A more gloomy and unsuitable location for a hospital could not have been selected. This ward contains eleven beds, four of which were occupied and one of these by a prisoner who had been confined since October, 1921, awaiting trial. In this interval he had lost forty pounds in weight. From his appearance and from information gathered from the attendant it would appear he was suffering from tuberculosis, but no examination of the sputum had been made, nor were we able to find in the record book any statement in regard to the nature of his ailment.

### Jail Hospital Conditions

Captain Westbrook, the jail warden, realized fully the insanitary condition of Hospital B and was strongly in favor of abandoning it and placing all prisoners requiring hospital care in Hospital A. He stated that he had been unable to do this because it would be necessary to employ three guards to be on duty at Hospital A, which is at present unguarded, and he had not been able to obtain an appropriation for paying these guards.

There is at present no provision for the isolation of contagious cases. While the institution has been unusually free from these diseases, the conditions are such with prisoners mingling during the recreation hours in crowded "bull pens" and confined together during the rest of the day in cells, that sooner or later an epidemic will develop, and provision should be made for meeting such an emergency. Captain Westbrook had already considered this matter and suggested that the "death chamber" might be used for this purpose inasmuch as it is unoccupied except on rare occasions and

then only for twenty-four hours. This room is large, well lighted, and could accommodate at least four patients. The only change needed would be the installation of a bathroom and this could be placed in the store opening off from this chamber. Inasmuch as there have been very few contagious cases in the hospital in recent years, it is quite likely that this chamber could still fulfil the function for which it was intended. In plans for a new jail, however, adequate facilities should be provided for the proper isolation of contagious cases. Even with the use of the "death chamber," the facilities for isolating patients are entirely inadequate and the health of every inmate in this institution is menaced by failure to provide suitable isolation quarters. A book is provided to keep a record of patients in the hospitals, but this is poorly kept and little information can be gained from studying it.

*Women's Hospital.*—The hospital connected with the women's department of the jail is all that could be desired, except for convenient toilet facilities. It is a clean, well lighted room with three comfortable beds. It is the one bright spot in the hospital situation at the institution. The lack of a toilet and bath is, however, a serious drawback and one that should be remedied without delay.

*Mental Cases.*—There is no provision at the present time for taking care of suspected mental cases. At the time the institution was visited there was a prisoner who had been in jail since last October, and it was uncertain whether he was a malingerer or whether he was actually insane. This man was kept in a damp cell on the first floor opposite Hospital B. He was without clothing except for a pair of trousers, as this was all he would keep on. There was no cot in the room and the whole environment was most undesirable. It brings up another question which should receive attention—namely, the long period of time in which prisoners are kept in jail before coming to trial. In cases of tuberculosis or of mental trouble, long detention may easily mark the transition of a curable into an incurable condition.

*Drug Addicts.*—There is no doubt that drug addiction is very common among the persons committed to the county jail. The lack of an adequate examination of all inmates on admission or subsequently thereto leaves persons of this sort distributed about the jail, undetected, only to become a source of infection and serious misconduct. The well known relation of

this habit to criminality and its tendency to induce vicious and reckless characteristics make it specially desirable to identify and, so far as possible, to isolate and treat its victims. Under existing conditions in the jail it will not be easy to deal adequately with this class of patients. But they should at least be weeded out from the general jail population and so disposed of as to render them subject to constant supervision and to humane treatment. It is possible that arrangements might be made to treat the more serious cases in the Washington Home or other institution for the treatment of drug addiction.

*Re-Examination.*—At the present time prisoners who are kept in the hospital for several months are never examined by the physician unless they make some complaint. Provision should be made for the re-examination of prisoners at no longer than monthly intervals in order to detect incipient disease. While this examination should include a general survey of the patient, special attention should be paid to the chest on account of the danger of tuberculosis in such an environment.

In conclusion we respectfully submit the following recommendations:—

### Recommendations Made

(1) The rule requiring examination of prisoners upon entrance should be more rigidly observed. To make such an examination and record the findings would require a minimum of ten minutes per person.

(2) The prisoner should be provided with clean underclothing following the initial bath.

(3) Hospital B should be immediately abandoned.

(4) A six-foot movable partition should be placed through Hospital A and an additional toilet and bathroom provided. One portion of Hospital A can be used for the isolation of tuberculosis patients. The addition of toilet facilities adjacent to the "death chamber" would be desirable so that this room would be available for emergency use as an isolation ward.

(5) Suitable quarters for mental cases should be provided. If this cannot be done at the jail, arrangements should be made so this group of patients might be taken to the County Psychopathic Hospital where they can be adequately studied and an early conclusion reached in regard to their condition.

(6) Better medical attention, and, if necessary, isolation of venereal cases should be provided.

(7) More complete records should

be kept of patients in the hospital.

(8) Laboratory facilities for some of the ordinary routine examinations should be provided.

(9) A full time physician, with one or more assistants, should be appointed to devote their entire time to looking after the inmates of the jail, thus enabling the inmates to receive proper medical attention and provide for monthly examination of all prisoners.

(10) A trained pharmacist should be provided to dispense simple remedies, to replace the trusty who now performs this function.

(11) The Chicago Institute of Medicine should be authorized to appoint a committee of three physicians who will make quarterly inspection of the jail and make a written report to the proper authorities.

(12) The inmates should be allowed more than the four hours for exercise in the "bull pens," in order to lessen the dangers of the present crowding and inadequate air space in the cells.

(13) A ventilator should be placed in the rear of each cell.

(14) There should be systematic extermination of the vermin in the cells.

(15) Clean sheets should be provided for each new prisoner when placed in a cell.

(16) Blankets should be cleansed and disinfected at intervals not to exceed one month.

(17) A sterilizing plant should be provided for the proper disinfection of clothing.

(18) A committee of dietitians should be appointed to make periodic inspection of food conditions and make recommendations in regard to the prisoners' diet.

(19) The plans for the new jail should make provision for the following hospital facilities and equipment:—(a) Laboratory facilities in order that some of the simpler examinations, essential in making a diagnosis, can be carried on. (b) Well lighted and well ventilated hospital space. In order to provide suitable isolation, this should be arranged in the form of separate wards of moderate size, rather than one large ward. In addition to this there should be a number of two or three-bed rooms which could also be used for isolation of special contagious cases. The number and size of these wards, and the number of the small rooms required would depend upon the size of the jail to be constructed. (c) Suitable isolation quarters for the mental, or suspect mental cases, unless it is decided that these can be taken care of at the

County Psychopathic Hospital, which would be by far the better arrangement from the standpoint of medical attention. (d) All cells arranged so there would be through-and-through ventilation, allowing a capacity of 500 cubic feet of air space for each inmate. (e) If possible, an outdoor yard

should be arranged where the prisoners could get exercise. If this is not feasible, then well lighted and well ventilated "bull pens" should be provided. (f) Suitable space and adequate facilities for making the preliminary medical examination. (g) A properly equipped dispensary.

## Girls in Summer Camps

BY ELLA L. BATES, R.N., SECRETARY BISBEE HEALTH CENTER, BISBEE, ARIZONA.

**M**ANY parents consider it their duty to send the boys of the family to a camp for the whole summer, or at least for part of the vacation period. They seem not to realize, however, that their daughters would enjoy a summer camp and would gain just as much from them physically and socially as their brothers. Oftentimes the mistaken idea that the girls would become homesick is a factor influencing parents to keep them at home.

Summer is the time of greatest physical growth. Freedom from conditions causing over-fatigue and the greater opportunity for outdoor life result in height and weight gains beyond those of other seasons. In a summer camp the child may become part of a larger and more inclusive whole than the home. He returns home with a broader vision and a better appreciation.

The summer camp affords an opportunity for simple living. The boy

or girl who enters a camp with some particular food prejudice usually learns to eat plain wholesome food. In both camp and nutrition work it has been found that girls are more difficult to influence and the incentive of the group facilitates suggestion.

The group spirit which the camp fosters makes such a life especially beneficial to girls. But a camp to be of value must be carefully selected; its directors must know the girls and be interested in them. The over-indulged child here learns through contact with others that it is not always feasible to gain her own way and that popularity does not lie in always obtaining her own desires.

The camp teaches health, confidence, independence, self-control,—foundations for a physically well and mentally alert manhood and womanhood. The girl and boy who gain weight in the nutrition class or summer camp show the results of sun,

Underwood & Underwood.

Girls enjoy summer camps just as much as their brothers. The group spirit inculcated in the open is invaluable as a foundation for health and social life.

air, light, and intervals of rest in their rapid growth.

Twenty-one girls were recently taken to camp. They followed a

Wide World Photos.

Increased physical vigor means to the girl confidence, independence, self-control.

regimen of early rising and quick dressing, definite meal times, rest period after the noon dinner, exercises, and early bed hour, with the result that every girl gained from two to ten pounds each. The group

showed quick adaptability, enjoyment in making new friends, and zest for adventuring. They returned home from their outing full of energy, all desiring to attend the camp next year.

To those who allow sympathy to overcome their judgment in the matter of philanthropy the following instance cited by the City of Detroit Department of Health should be an object lesson as to the futility of private philanthropy:

Herman Kiefer Hospital opened her tuberculosis ward to a man early in 1918. He stayed several months and then left without permission. He found it more to his liking to enlist the sympathy and financial support of private individuals. He asked for money to take him west so he could be cured of tuberculosis. He got it, got it many times, and he abused the kindness of the people who helped him. Individualistic philanthropy did this since 1918: It sent him to Colorado and return three times; it sent him to Illinois and return three times; it sent him to Minnesota once, and to Iowa once; it helped him into Eloise, Herman Kiefer, and the Detroit Tuberculosis Sanatorium about ten different times. Last year Detroit business men gave him \$486.00 in three months.

Detroit possesses a clearing house for such cases in its Department of Public Welfare.

measures do not stop here. The necessary recreation, individual requirements of nutrition, social studies leading to necessary readjustments, and minute attention to minor physical ailments that would be overlooked in civil practice, is a part of the health regime of the institution. The total admissions for 1921 were 249, and 198 patients were discharged during the year.

Suitable occupation and graduated exercise are provided in every case, the objective being complete rehabilitation in every case finally discharged as cured. Supervision extends beyond the walls of the institution. Relapse due to a return to an unsuitable environment or to inappropriate pursuits is a discouraging feature where follow-up work is not done. It is poor economy to invest seven hundred dollars for nine months of sanitarium care, a fair average in the cases cared for, and then dismiss a patient with no further concern as to his welfare. A survey is made of all patients as to occupations from which they come, and future plans include the provision of industrial establishments on lines adapted to the needs of ex-patients as the greatest step in constructive rehabilitation.

The institution is under the able direction of Dr. I. N. Bronfin as superintendent, supported by a medical advisory board and consulting staff of physicians and surgeons.

## Largest Jewish Sanatorium

**T**HE Jewish Consumptives Relief Society, with the dedication in July of the new central building at the Denver Sanatorium, becomes the sponsor of the largest Jewish sanatorium for tuberculosis in the world. It is not merely in the size of the project, however, that the institution is distinguished, for the whole scheme of organization is designed to meet the fundamental needs of the patients. The institution is a school for tuberculous people, maintained and supported through the good will of

American Jewry, and is peculiarly adapted for the treatment of a disease that requires months and years of medical care, and an equal period of training the patient how to become well and how to keep well.

One of the most wholesome influences of the institution is the method of government by which each patient assumes certain responsibilities of self-government and is made to feel himself an important member of the community. Adequate medical care is provided in every case, but curative

A Vocational Guidance Bureau was opened in Prague in May, 1921, which so far has devoted itself to consultations on industrial occupations and crafts. A woman advisor talks over the child's choice of occupation with him and with his parents. The decision as to the suitability of the occupation is based upon information thus obtained and upon medical and psychological tests given at the Labor Academy. Between May 1 and September 30, 1921, the office was consulted by 500 school children.

With the dedication of a new central building costing \$350,000, the Denver Sanatorium, Jewish Consumptive Relief Society, becomes the largest Jewish tuberculosis sanitarium in the world. Cultural requirements as well as physical needs receive attention here, and the system is such that the patient does not feel he is out of the world while his cure is progressing.

# An Experiment With Malnourished Children

By GERTRUDE GATES MUDGE, M.A., NUTRITION SPECIALIST, AND HELEN FRANCES RICH, B.S., NUTRITION DIRECTOR, NEW YORK CITY.

THE interest in malnutrition among children has grown with great rapidity within recent years. It has come to be considered not only a medical but also an educational problem. Specialists from many fields have allied themselves with this phase of child welfare work.

This brief report is submitted as constituting another method of approach to the malnutrition problem. It outlines the first of a series of experiments undertaken in order to ascertain the utility comparative value of fluid milk and condensed milk in the treatment of undernourished children.

The site of the experiment was a small New Jersey City within commuting distance of New York. From each of two grammar schools a group of sixteen children was recommended by the school physician. The two groups, consisting of thirty-two children (boys and girls), when weighed and measured were found to averaged 13 per cent below normal, the average for Group A being 9¾ pounds, and for Group B being 7¾ pounds. Children of varying ages were included; the average for Group A being eight years and for Group B being seven years.

The experiment was conducted for a period of twelve weeks, from December 1, 1921 to March 1, 1922, thus including not only the disrupting holiday season but also those months in which, according to Dr. William T. Porter<sup>1</sup>, the growth increment is markedly less than in the fall season of the year.

Educational, nutritional, and health work was carried on with both groups. Weekly classes were held during school hours for one school period of about forty minutes. At this time the children were weighed, the weights being recorded on tags which the children were urged to take home to their parents. Organized nutrition lessons were presented each week at which time health rules previously presented were reviewed and a new lesson given. The lessons emphasized the value of milk, of leafy vegetables, of fresh and dried fruits, and of coarse breads and cereals in the daily diet. Stress was placed upon proper habits

of hygiene such as, long hours of sleep, plenty of fresh air during the day and night, and dental hygiene. Illustrative material in the nature of posters, health play, and songs were used to stimulate the interest of the children in their weight gains and improved physical conditions. A milk playlet was presented by the nutrition class children, first at a morning assembly and later for the benefit of the Parent-Teachers-Association.

## Reaches into the Home

This educational work was conducted not only in the schools but also in the homes of the children which were visited at least three times each during the experiment. By this means the cooperation of the parents in the health crusade was more easily obtained and at the same time it was possible to check up on the health environment of the children. That the economic status and home conditions of the two groups were distinct factors in this experiment is shown by the comparative gains made. The children of Group A came from homes higher up on the social scale. Sufficient

food was available and the parents were fairly intelligent. However, there was a decided lack of discipline and the omission of the right kind of influence in the home is reflected markedly in the rate of gains in weight. The children failed to give hearty response to the stimulus which the nutrition teachers tried to arouse in the nutrition and health work.

The children of Group B represented homes of a supposedly lower standard. There was a decided lack of food in many cases and the parents were of mediocre intelligence. In this instance, however the greater cooperation was probably due to a keener appreciation by the parents of the mid-morning feedings and a higher value placed on the lessons in nutrition and health. Group B as a whole was much more interested in their weight gains and showed more real enthusiasm for the class work, than did Group A.

Social and medical histories were secured for each child, the latter being limited to that information available from the school record. Follow-up work on the correction of physical

Typical chart selected at random from Group A. The normal rate of gain is in accordance with standards recommended by the Child Health Organization. After a few fluctuations, Olive B, made steady progress, gaining more than was anticipated during the period of observation.

1. Porter, William T.: The Seasonal Variation in Growth of Boston School Children, Am. J. Physiol., May 1, 1920, pp. 121-131.

defects was attempted by the nutrition workers, but efforts in this direction were greatly handicapped due to the overcrowded tonsil and dental clinics of the city.

Mid-morning school feedings were given to both groups for five days a week during the experimental period. The children were excused from classes for a fifteen minute period each day for the feedings. Group A was given one and one-fourth cups of the fluid milk the energy value of which was about 196 calories. Group B was fed an equal quantity of diluted condensed milk of the same caloric value as the feedings of fluid milk. All children of both groups received about two tablespoonfuls of orange juice daily, making the total food value of each feeding approximately two hundred calories. Individual charts are reproduced to show the normal and actual weight curves. This graphic record of progress was watched daily and proved to be of great interest both to the children and their teachers.

#### Typical Case Records

*Olive B., Group A.* (Plain milk pasteurized.)—English. Both parents were intelligent but not cooperative. Home was bright and cheerful. Olive was in the adolescent period, and was pale, thin, and very badly nourished. She was the youngest in a family of four children and was spoiled and undisciplined. Her mother recognized her faulty dietary and health habits but was too indulgent to correct them. Interest was easily stimulated by the nutrition workers. Olive became a staunch member of the, "At Least a Pint Of Milk A Day," crusade and took a prominent part in the health play. Her window was kept wide open at night overcoming the "two-inch-window-raising" habit. She eagerly reported changes in her daily diet habits, mentioning fresh fruits, green vegetables, and cereals which she was beginning to eat. Her gain for the three months period was one and three-fourths pounds in excess of the expected rate of gain for that period of time.

*Dorothy L., Group B.* (Condensed Milk sweetened).—American. Both parents were of mediocre intelligence. Home was plain and neat but showed evidence of forced economy. Dorothy was in adolescent period, tall, extremely pale, thin and very self-conscious. She was the third child in a family of six children. Her mother realized the daughter's malnourished condition and encouraged her to correct her faulty health habits. The par-

ents were very appreciative of the milk feedings at the school and of the class instructions. Dorothy was easily converted into an enthusiastic member of the nutrition class. After

age gain per child for Group B was 0.39 pounds more than for Group A.

The resulting figures of this preliminary experiment may be taken to indicate that sweetened condensed

Dorothy L. exhibited some ups and downs, under less favorable conditions, but with consistent cooperation was able to gain  $2\frac{1}{4}$  pounds more than the expected rate of gain for that period of observation.

weeks of mid-morning feedings and instruction she began to change in appearance as well as in weight. Her heightened color, added flesh, and increasing neatness of dress made her look like a different child. During this period she suffered from numerous colds and headaches but by playing the game untiringly and giving up many bad health habits she was able to show a gain in weight, at the end of the experiment, of two and one-fourth pounds over the expected rate of gain for that period of time.

Results obtained were as follows:

Total gain in weight of group A (whole milk) 28.37 pounds.

Total gain in weight of Group B (condensed milk) 34.62 pounds.

Average gain in weight per child in Group A, 1.77 pounds.

Average gain in weight per child in Group B, 2.16 pounds.

Expected gain per month<sup>2</sup>, 0.50 pounds.

The total gain in weight for Group B which had the condensed milk feedings exceeded the total gain of Group A by 6.25 pounds, also that the aver-

milk has a par value with fluid milk (pasteurized) in the treatment of malnourished children of school age. Similar experiments now under way tend to verify the results herein reported.

"State Parks" by Harold A. Caparn, Landscape Architect, New York City, is an account of the movement in the various states to preserve land for recreational purposes. It is published as a supplement to the *Municipal Review*, November, 1921. To date the following twenty-six states have state parks: California, Connecticut, Florida, Georgia, Idaho, Illinois, Indiana, Iowa, Kansas, Maine, Massachusetts, Michigan, Minnesota, New Jersey, New York, North Carolina, North Dakota, Ohio, Pennsylvania, Rhode Island, South Carolina, South Dakota, Texas, West Virginia, Wisconsin, and Wyoming.

The June issue of *Physical Training*, published by the Physical Directors' Society of the Young Men's Christian Association of North America, contains the complete outline of the physical education program.

2. Standard recommended by the Child Health Organization.

## Europe's Cooperative Homes

HOW thousands of families in ten European countries, independent of politics and charity, are solving the housing problem cooperatively is told by Agnes Dyer Warbasse in *The American Review of Reviews*. In Switzerland, England, Scotland, Wales, France, Belgium, Holland, Denmark, Germany, and Czechoslovakia, the plain people have organized as part of the world cooperative movement which has a membership of thirty million families in twenty countries. Through their cooperative societies they are producing and distributing most of the necessities of life free from profit and exploitation, adulteration, benevolence, politics, and red tape.

The contrast afforded by the well regulated European cooperative building societies owning their own supply plant with the American system of building for personal profit is illuminating. Speculative building for individual profit which has resulted in trade combinations in the United States, in legal restraints, and even penitentiary sentences has been either totally discarded or is naturally disappearing in Europe, Mrs. Warbasse states.

Apartments in Copenhagen cooperative buildings rent from \$14 to \$37 a month depending upon the size of the apartments which range from three rooms and bath to six rooms and bath. The one visited by Mrs. Warbasse, located on the leading boulevard of the city, was built on the principle of a hollow square around a garden court covering 90,000 square feet. Each room in the 215 apartments faced either the street or the courtyard. Fire proof stairs made fire escapes unnecessary; all rooms were lighted with electricity; floors were hardwood; and the white tiled kitchen was completely equipped with gas stove and modern plumbing.

The courtyard which is required by Danish law was laid out with an eye for esthetic effect as well as utility. A high clock tower with the clock's dial facing four ways stood in the center of a rose garden laid out in the form of a Greek cross. At the four corners were children's playgrounds with swings, seesaws, athletic boards, sand boxes, and sheltered seats for the mothers. A cement walk encircling the garden and playground afforded the boys and girls a place to ride their bicycles, skate, or play games.

Berlin artisans live in this decorative cooperative house located in one of the congested districts. Three hundred and thirty-five families are comfortably housed in this apartment alone.

The homes are built by the members of the association composed of the workers, or by the municipality in some instances. Each tenant of such a home colony must become a member of the association and pay as membership fee the equivalent of one year's rent for which he receives 4 per cent interest. This constitutes his share capital.

Government loans are sometimes made to cooperative housing associa-

tions which are producing homes not for speculation or private gain, 20 per cent of the valuation being loaned by the city and 20 per cent by the district of Copenhagen. This constitutes a twenty year loan which will be cancelled at that time if the housing association has lived up to its original purpose.

Municipal houses, on the other hand, are built for the city and rented to a more or less itinerant class of tenants who are unable or unwilling to assume the responsibilities attached to membership in a cooperative association. Rents in municipal houses are higher in order to support the salaried officers who manage them.

The difficulties encountered in the United States of obtaining bricks, lumber, cement, plumbing supplies, etc., are obviated in Europe by the cooperative associations owning and managing their own factories. Two brick plants supply nearly five million bricks a year, all cement is bought from the cement workers' cooperative factory in Jutland, and cement trimmings and castings, are made in an association-owned factory in Copenhagen.

The Workers Cooperative Building Society is the central organization into which the members invest their capital for home building. Each housing group is a department of the main society and is run by the householders. The rent is collected and repairs and upkeep are made by a local committee who is responsible to the main society for the care and financing of each building.

Cooperative apartment in Copenhagen surrounding a court 90,000 feet square in which are located gardens, playgrounds for children, and shaded walks.

# Health of Working Children

THE Massachusetts Department of Labor and Industries is publishing a form for use in the examination of children applying for employment certificates. This form covers the main points given in the one recommended by the Children's Bureau, but is much less detailed. The Department recommends that school physicians assigned to examining children for health certificates use this schedule. Copies will be furnished on application.

At the present time there is no standard form for this purpose in use in the state. A few physicians have their own records; but in the majority of instances no form is used so no permanent record is kept. It is important that the results of the examination should be recorded and kept on file in the office from which

the employment certificate is issued. By this means it is possible, when the child returns for another certificate, to check the examination with the result of the previous one, to ascertain whether defects noted at the former time have been corrected, and to secure some information as to the effect of the work on the child's health.

A standard form for all issuing offices is desirable, in order that there may be greater uniformity in practice throughout the state, and in order to insure that the examination made covers all the essential requirements. It is hoped that the use of the proposed schedule will assist in bringing about these results, will secure a more thorough and careful examination of children applying for employment certificates than is the case at the present time.

The Department is also preparing a handbook explaining the procedure in issuing employment and health certificates and badges for street trades. This will contain a section on the health certification of working children with reproduction of the new forms.

## The Heart and Life Insurance

Organic disease of the heart occupies the first place among the causes of death among the general population in the registration area of the United States exceeding even the mortality from tuberculosis. Between two and three per cent of all applicants for life insurance are rejected for this cause, and it is probable that from 10 to 15 per cent of deaths of insured people are due to organic disease of the heart, according to Dr. Lewellys F. Barker, in the *National Underwriter*.

Though it is the prevalence of valvular defects due to endocarditis that is alarming among young people, it is the occurrence of other forms of cardiac disease that causes concern when older persons are studied. More should be done, and that speedily, says Dr. Barker, to ascertain the exact causes of the toxic degenerative diseases of the heart muscle and of the vascular diseases associated with chronic arterial hypertension.

In general medicine there is less concern than formerly by the mere discovery of a murmur, even when a study of the heart murmur reveals it as due to organic disease of a valve, and emphasis is shifting to heart muscle functions. The condition of the heart most often responsible for early and sudden death in men over forty is angina pectoris, a condition difficult to detect. Once an anginal attack has occurred, the sufferer is insurable only as a gamble.

The suggestions offered include the use in routine physical examinations of such modern diagnostic methods as reveal disordered function. Safety for the insurer in estimating the risk taken in a given case requires a comprehensive diagnostic survey of every substandard risk. Internists, according to Dr. Barker, will look forward eagerly to the prognostic deductions of medical actuaries, when in the future they will have had opportunity to analyze the effects upon longevity of various deviations from normality in the heart recognizable by the newer methods of examination. It is upon early recognition and such correlation that our best hope of preventive methods depends.

FORM M 1922

MASSACHUSETTS DEPARTMENT OF LABOR AND INDUSTRIES

RECORD OF PHYSICAL EXAMINATION OF CHILD APPLYING FOR EMPLOYMENT CERTIFICATE

DATE \_\_\_\_\_

NAME	ADDRESS	SCHOOL	GRADE
INTENDED EMPLOYER	ADDRESS	INDUSTRY	OCCUPATION
1. SEX, M. F.	2. COLOR, W. C. O.	3. BIRTHPLACE OF CHILD	4. OF MOTHER 5. OF FATHER

TEMPORARY (SP) REMARKS: I AM NOT ACQUAINTED WITH THE PROCEED ON WHICH THIS CHILD IS TO BE ENGAGED. CROSS OUT STATEMENT WHICH DOES NOT APPLY.
CERTIFY THAT I HAVE EXAMINED THIS CHILD AND THAT THE FINDINGS ARE AS ABOVE STATED. SIGNED: _____ M.D., EXAMINING PHYSICIAN (THE SCHEDULE SHOULD BE MADE OUT IN DUPLICATE BY USE OF CARBON SHEETS, AND ONE COPY SENT TO THE DEPARTMENT OF LABOR AND INDUSTRIES, STATE HOUSE, BOSTON)		

### INSTRUCTIONS TO PHYSICIANS FOR FILLING IN RECORDS OF PHYSICAL EXAMINATION OF CHILDREN APPLYING FOR EMPLOYMENT CERTIFICATES

- IN FILLING OUT RECORD BLANK USE CHECK (A) WHERE DEFECT OR ABNORMALITY IS FOUND, AND DASH (-) WHERE CONDITION IS NORMAL WHERE ITEM IS MARKED (SP) SPECIFY DEFECT OR CONDITION INDICATED
- GRADE**—ENTER GRADE COMPLETED
  - INDUSTRY**—SPECIFY, AS "COTTON MILL," NOT "TEXTILE"
  - OCCUPATION**—SPECIFY, AS "COOPER" NOT "MILL HAND."
  - COLOR**—WHITE-COLORED-OTHER
  - BIRTHPLACE OF CHILD**—COUNTRY OF BIRTH.
  - BIRTHPLACE OF MOTHER AND FATHER**—COUNTRY OF BIRTH
  - HEIGHT**—TO BE ENTERED TO NEAREST QUARTER INCH. THE CHILD SHOULD BE MEASURED WITHOUT SHOES.
  - WEIGHT**—TO BE ENTERED TO NEAREST QUARTER POUND. THE CHILD SHOULD BE WEIGHED WITHOUT SHOES AND OUTER CLOTHING.
  - SIGNIFICANT MEDICAL HISTORY**—BRIEF NOTATION OF PREVIOUS ILLNESSES.
  - GENERAL PHYSICAL CONDITION**—TO BE DETERMINED BY SUCH FACTORS AS MUSCLE TONE, THE COLOR OF THE SKIN AND MUCOUS MEMBRANES, AND THE RELATION TO EACH OTHER OF THE HEIGHT, WEIGHT AND AGE. CHECK ON RECORD CARD CONDITION INDICATED AS FOLLOWS: EXCELLENT, GOOD, FAIR (REQUIRING SUPERVISION), POOR (REQUIRING MEDICAL ATTENTION).
  - MATURITY APPARENTLY ATTAINED**—EXAMINER'S IMPRESSION.
  - SKIN**—PARASITIC DISEASES. HERE NOTE PEDICULOSIS, SCABIES, ETC.
  - EYES**—A SCRAPATE EXAMINATION AND RECORD OF THE VISUAL ACUITY OF EACH EYE SHOULD BE MADE. THE SNELLER OR SIMON TEST CARD BEING USED. ABILITY TO READ THE TWENTYFOOT LINE AT A DISTANCE OF TWENTY FEET TO BE CONSIDERED PERFECT AND RECORDED AS 20/20. RECORD IN FRACTIONS, THE NUMERATOR INDICATING THE DISTANCE BETWEEN CHART AND CHILD, DENOMINATOR INDICATING LINE READ BY THE CHILD (FIGURE KNOWN AT SIDE OF CHART). IF CHILD IS UNABLE TO READ ANY OF THE LETTERS CORRECTLY AT TWENTY FEET, MOVE HIM TOWARD THE CHART UNTIL HE CAN SEE THE TOP LETTERS, AND MEASURE DISTANCE BETWEEN HIM AND THE CHART AND RECORD AS TEST. IF CHILD IS WEARING GLASSES, THE TEST TO BE MADE BOTH WITH GLASSES ON AND WITH GLASSES OFF. A CHILD WITH VISION OF 20/30 OR LESS IN EITHER EYE SHOULD BE REFERRED TO AN OCUJIST.
  - EARS**—EACH EAR TO BE TESTED SEPARATELY, USING THE WHISPERED VOICE AT A DISTANCE OF TWENTY FEET. CHILD SHOULD STAND WITH EAR BEING TESTED TOWARD EXAMINER, AND OTHER EAR COVERED OR EXTERNAL CANAL OCCLUDED. IF HEARING IS DEFECTIVE, THE EXAMINER SHOULD ADVANCE SLOWLY TOWARD THE CHILD UNTIL HE CAN HEAR THE WHISPERED VOICE. MEASURE DISTANCE BETWEEN EXAMINER AND CHILD, AND RECORD IN FRACTIONS. 20/20 BEING NORMAL. INABILITY TO HEAR THE WHISPERED VOICE AT TEN FEET OR LESS SHOULD BE CONSIDERED DEFECTIVE HEARING AND SHOULD BE REFERRED TO A SPECIALIST.
  - TONSILS**—ENLARGED—DISEASED. VISUAL EXAMINATION OF THE THROAT TO BE MADE WITH THE USE OF TONGUE DEPRESSOR.
  - CHEST**—EXAMINATION OF THE CHEST SHOULD ALWAYS BE MADE ON THE BARE SKIN.
  - LUNGS**—TO BE EXAMINED BY PERCUSSION AND AUSCULTATION, USING THE STETHOSCOPE. ANY ABNORMAL CONDITION TO BE SPECIFIED.
  - HEART**—TO BE EXAMINED WITH STETHOSCOPE. HEART DISEASE—SPECIFY VARIETY OF ORGANIC DISEASE AND COMPENSATION.
  - ABDOMEN**—PRESENCE OR ABSENCE OF HERNIA TO BE DETERMINED BY QUESTIONING AND PHYSICAL EXAMINATION WHERE SUSPECTED. STATE WHETHER FOUND OR NOT, WHETHER TRUSS WORN, AND WHETHER OR NOT CHILD NEEDS OPERATION.
  - ORTHOPEDIC DEFECTS**—GENERAL INSPECTION OF THE BODY TO BE MADE. ALL DEFECTS, INCLUDING IMPAIRED MOBILITY OR DEFECTS OF POSTURE MUST BE SPECIFIED. NECESSARY MEASUREMENTS TO BE MADE WHEN INDICATED BY ABNORMAL FINDINGS.
  - TREATMENT RECOMMENDED**—NOTE TREATMENT RECOMMENDED FOR CORRECTION OF DEFECTS, AND TO WHAT AGENCY, IF ANY, CHILD IS REFERRED FOR TREATMENT. FOR EXAMPLE, REFERENCE TO DENTIST IN CASE OF DEFECTIVE TEETH.
  - CERTIFICATE**—CHECK AS INDICATED AND SPECIFY PHYSICAL DEFECT CAUSING RECOMMENDATION OF REFUSAL OR OF PROVISIONAL CERTIFICATE ISSUE.
  - REMARKS**—EXAMINER TO CROSS OUT "AM" OR "AM NOT," INDICATING IGNORANCE OR KNOWLEDGE OF THE PRECISE NATURE OF THE WORK FOR WHICH THE APPLICANT IS TO BE EMPLOYED.

\* THE DEPARTMENT OF EDUCATION WILL FURNISH A NEW VISUAL TEST CARD FOR USE IN THE PUBLIC SCHOOLS IN THIS STATE

This blank form is the standard set for use in Pennsylvania for the examination of working children. The card folds in the middle and is printed in a manner to facilitate ease in referring to files.

# KOTEX

## Wherever nice women gather

**L**OW PRICE sometimes causes people of means and refinement to hesitate in buying a new article. Kotex is inexpensive, yet women who can afford the best were first to accept Kotex.

Kotex is sold wherever women trade—in drug, dry-goods and department stores. And in several different departments in many of the latter. No counter conversation necessary. Ask for "a box of Kotex."

Girls and women active in athletics, dancing, or business, find in Kotex a safeguard that insures their poise and comfort at all times. Kotex is cool in warm weather and always easy to dispose of.

Traveling or at home, Kotex is almost indispensable. It solves a difficult laundry problem for nice women—rich and poor alike.

It is packed in plain blue box free from descriptive matter, the name the only printing. The first box usually—the second box always—results in the discovery of a new comfort, a new convenience, a new economy, a new habit.

Keep Kotex always on hand—ask for them by name.

Regular size, 12 for 60c

Hospital size, 6 for 45c

Samples of either size, prepaid, free.

*Kotex cabinets are now being distributed in women's restrooms everywhere—hotels, office buildings, theatres, and other places—from which may be obtained one Kotex with two safety pins, in plain wrapper, for 10 cents.*

Cellucotton Products Co., 166 W. Jackson Boul., Chicago

New York Office: 51 Chambers Street

Factories: Neenah, Wisconsin

**INEXPENSIVE, COMFORTABLE, HYGIENIC and SAFE — KOTEX**

# The Prevention of Myopia

**C**ONGENITAL defect in the eye, causing myopia, or short-sightedness, is considered by F. W. Edridge-Green, in a recent issue of the *Lancet*, to be very rare in comparison with the acquired defect. Older authorities believed that prolonged convergence of the eyes for near work caused pressure upon the eyeball and in some way caused its elongation, thus producing shortsightedness, but this author, on the basis of a detailed examination of some thousands of cases of myopia, says it is not proved in a single case that myopia had been either caused or increased by the use of the eyes for near work. The argument that the eyesight of the laboring classes is good simply because comparatively few of the working populace wear glasses is no proof that their sight is better than that of professional classes. A barrister will wear glasses for the correction of a trivial defect—as, for instance, 0.25 diopter of myopic astigmatism, whereas a dock laborer with very high myopia of —25 diopters will not wear them and does not feel the need of them.

Again, many children become myopic without having used their eyes particularly for near work. Even when the selected occupations have been given—composer, lithographer, etc.—it will be found that the myopia was not contracted in their occupations, but that the occupation was chosen because of short sight. The incidence of myopia is given as 17 per cent in urban districts, 20.5 per cent in rural districts, and 26 per cent in mining and manufacturing districts.

A common cause of myopia is asserted to be hereditary. Edridge-Green suggests that the hereditary defect may be a special weakness of the sclerotic to give way under pressure. Among the exciting causes this author believes that first place must be given to certain diseases, as measles, whooping cough, and bronchitis. The relation in the case of measles he believes to be very definite and to account for large numbers of non-progressive myopia.

A significant relation between the occupation before, during, and after the onset or increase of myopia was found to exist between myopia and certain occupations, namely, those associated with heavy lifting in a stooping position, especially in those who appear to take no other exercise, as, for instance, carters, who have at intervals to carry heavy weights. A

boy will state that he had no trouble with his eyes until after he left school; but in his employment, where he had continually to lift heavy boxes, he began to get more and more shortsighted. Again, in many of those having a sedentary occupation the form of exercise selected will be found to be one which would act in the way described, namely, boxing, wrestling, cycling, rowing, or digging. Coughing appears also to be a potent cause. A boy will state that he had nothing the matter with his eyes until after a very bad attack of bronchitis, when, upon returning to school, he is found to be myopic. Numerous cases are cited as resulting from whooping cough.

## Causes of Myopia

Edridge-Green reports a case of myopia in one eye and a detached retina in the other as resulting in a man of good sight from one afternoon of excessive strain. In the case of a young musician, whose musical work caused no eye discomfort, so-called "rests" with physical work on a farm resulted in pronounced myopia.

The recommendations which have been made by ophthalmic surgeons—namely, to avoid reading and writing in a stooping position, and to secure good lighting, ventilation, and other

hygienic conditions—he considers advisable, but they do not seem to produce much effect in the prevention of myopia. In diseases which are followed by myopia, such as measles and whooping cough, special care should be taken of the eyes, especially in those with an inherited tendency to myopia; and during convalescence the exercises should be very carefully regulated, those forms of exercise which raise the intra-ocular pressure should be avoided.

In the training of children in whom the eye is growing, when the coats of the eye are much softer than in the adult, he recommends those exercises which cause pressure should be avoided. For instance, the exercise in which the child is prone and raises itself up and down on its hands, with its eyes pointing downwards, should be abolished. The student who takes his exercise intermittently should particularly avoid those forms which produce increased tension in the eye, such, for instance, as riding up steep hills and bending forward when cycling, using dumb bells, and lifting heavy weights.

Any occupation which involves heavy lifting is not considered suitable for a myopic. It is particularly in those who have sedentary occupations, who are not in fit physical condition, and who have an hereditary tendency to myopia, that these forms of exercises should be avoided.

## A Sanitary Washing Fountain

Hygienic, attractive in design, and economical in space and the number accommodated, is this washfountain built of highly polished ground marble and concrete. The water is controlled either by a foot or hand lever with soap containers as part of the construction. The installation is used in railway stations, public buildings, and industries where large numbers must wash in a short time.

*A flexible shoe for your flexible foot*

Nature, in her wisdom, designed your foot arch to flex when you walk. Why restrain it in shoes that are rigid and without natural lines? "The foot is like a cantilever spring," wrote a noted doctor. "The Cantilever is the most comfortable shoe I have ever worn," said a trained nurse; and another woman said, "In Cantilever Shoes I feel as though I were flying."

It is because of the *flexible shank* and *natural lines* of the Cantilever Shoe that you will derive such comfort from it. And because of its graceful appearance and its harmony with this Spring's shoe styles you will see it worn wherever daytime costumes are worn. Fine workmanship, splendid materials and reasonable prices add to make the Cantilever desirable.

The graceful carriage and youthful walk of the Cantilever Woman are often admired. Her feet are free. She walks naturally, with a minimum of effort. Flexing with

every step, Cantilever Shoes make her feel as though she wore the wings of Mercury.

Though you may not be conscious of it, there are few things that spoil a good disposition quicker than shoes that nag you. Nerve strain, leading to backache, headache, and even to pains like those of rheumatism, may be caused by high heels and by shoes that bind and restrict the feet. Many writers on health and beauty subjects are now pointing out the importance of a woman's shoes in respect to her health, happiness, and personal attractiveness.

You were given two marvelously constructed feet. At the nearest Cantilever Store, try on a pair of shoes suited to their needs. Keep your feet well and spare yourself the misery that has come to so many women. If wrongly designed shoes have already begun to injure your feet, a change to Cantilevers will help them. Weakened arches will be strengthened by proper exercise; your improved circulation will make you feel better and look better.

If none of the listed dealers is near you, write the manufacturers, Morse & Burt Co., 1 Carlton Avenue, Brooklyn, N. Y., for a nearby dealer's address and for the Cantilever Booklet, which tells some things you will be glad to know about your feet.

**Cantilever Shoe**

### Health Examinations

The "Listening Post" (medical office) at the Keep Well House of the New Haven Health Center in seeking ways to popularize its physical examinations has recently prepared a certificate, the reproduction of which is shown below. It has been felt that the significance of the thorough physical examination could be more effectively impressed upon individuals if they could carry away a record of the examination. Consequently, an attractive certificate 8x10 inches in orange and black signed by

These have been distributed throughout the shops and factories of the district, and have brought to the attention of many for the first time the idea of a health examination.

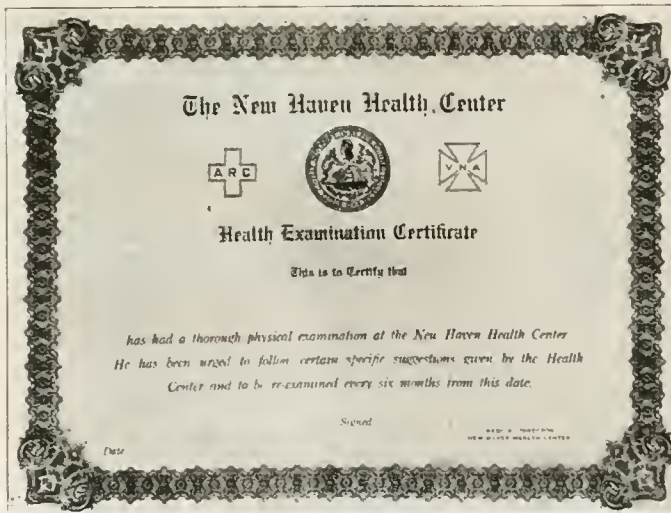

### New Jersey's War on the Mosquito

The Board of Conservation and Development in New Jersey has recommended that one million dollars be appropriated for a five year campaign against the mosquito. The report of the Board, just issued, in arraigning

mills, and homes are now standing, he said, upon reclaimed marsh land which a few years ago was considered uninhabitable. Consummation of the work will probably require a round million of dollars, the Board of Conservation and Development maintains, and the job will be done well only when it is done thoroughly, counties cooperating with the state, as in road building. If the Legislature has not been convinced that the public welfare would be served by an appropriation of approximately one million dollars, it is because the rural mind yields but slowly to enlightenment, the country's representatives do not mind mosquitos, and the increased valuation argument is too subtle for them. But the reform is marching on. New Jersey from Lake Marcia, up near Port Jervis, to Cape May Point will some day be free from mosquitos.

The Wisconsin state board of health has appointed Miss Aimee Zillmer of Milwaukee as assistant in education for lecture work in social hygiene and related subjects. Miss Zillmer's last work was with the White-Williams Foundation at Philadelphia.

### S. Josephine Baker Honored

Facsimile of health examination certificate furnished by the New Haven Health Center.

International Newsreel.

A dinner has recently been given to Dr. S. Josephine Baker, director of the Division of Child Hygiene, in the Department of Health, New York City, attended by representatives of many organizations and by many prominent individuals, commemorating the completion of twenty years of service by Dr. Baker. Under her administration the Bureau has grown to maintain sixty-eight baby health stations that serve about sixty thousand babies each year and, in round numbers, one million school children come under the care of the doctors and nurses in the public and parochial schools. The outstandingly good work in this field in New York City is largely due to the vision of Dr. Baker, and the extension of the child hygiene movement throughout the country.

the medical director of the Health Center is now given to individuals who have been thoroughly examined. On the reverse side of the certificate the following personal notes are recorded: (1) The general condition of the individual at the time of the examination; (2) the notation of the specific physical defects; (3) the specific hygienic advice which the individual is urged to follow.

We have been gratified to see how favorably the certificate is received, and we believe that it will serve as a reminder to the individual to return periodically for examination. It will also serve to remind him of the findings at the time of the examination, which he is liable to forget unless they are of a serious nature requiring immediate attention.

Popularization of the idea of periodical health examination remains one of the outstanding challenges to public health administrators. One of many methods used in the Keep Well House has been the preparation of a poster calendar, 18x21 inches, printed on a pale blue background with black ink and touches of red.

the mosquito as a pest and as a health menace from the Tropics to the Arctic Circle, shows that the mosquito is not a necessary evil, that it readily lends itself to control, and that the incidence of malaria fluctuates with public effort—and public appropriation—for its extermination. The report is a valuable document in the hands of health officers in the figures adduced to show that it is money in the community's pocket to carry on a mosquito campaign, no matter what it costs. The New Jersey Board of Conservation and Development estimates that by clearing the state of mosquitos the value of property would be increased by five hundred million dollars in twenty years.

On March 1 the New Jersey Mosquito Extermination Association held a three days' convention at Atlantic City. The annual meeting of this body is the first sign of Spring in the southern part of the state. The treasurer of the Association calculated that an expenditure of \$750,000 would complete the work of which the counties, spending their own money, have made a beginning. Factories,

## This Is a Weak Foot—

A Condition  
Most  
Prevalent  
Among  
Women

The fashionable types of shoes, pointed-toe hosiery, excessive use of the feet in walking or standing, pregnancy, heavy weight bearing, etc., are responsible for the vast number of cases.

Remove predisposing cause and apply mechanical treatment and corrective foot exercises. It will help you to build a reputation in your locality. These foot troubles are found everywhere.

Successful orthopedists and general practitioners are prescribing

## *Dr Scholl's* *Corrective Foot Appliances*

which have now been placed in leading shoe stores and surgical instrument houses throughout the country.

These dealers have also been in-

structed in the proper method of adjusting appliances to the foot and shoe in accordance with the principles of the inventor and designer, Dr. Wm. M. Scholl.

Write for Pamphlet—"Foot Weakness and Correction for the Physician," and chart of corrective foot exercises. The subject will amaze you.

## Immunity in Infective Diseases

It is a little more than twenty years since the appearance of Elie Metchnikoff's "L'Immunité dans les maladies infectieuses" (Paris, 1901). The translation from the French by Professor Binnie of the Pathological Department of the University of Cambridge appeared from the Cambridge University Press four years later, and a reprint of this English edition in 1907. Despite the passage of fifteen years since the appearance of the last edition, fifteen years which have been pregnant with important advances in the medical sciences, it is a pleasant task and still apropos of current interests to re-view this book which (in his own words) "sums up the labors of twenty-five years" of one of the most renowned disciples of Louis Pasteur, of one of that noble land who labored by the Master's side and who assisted without stint in the upbuilding of that House in Paris in whose library stands the urn that holds his ashes. It is not rash to assert that in these fifteen years there have been only few contributions in humoral or cellular physiology of importance equal to that contained in "Immunity in Infective Diseases." With the appearance of this volume came the convincing proof (1901) that neither the humoral nor the cellular conceptions of the immune reactions were, in themselves, sufficient to account for the phenomena which had been observed, that there was no inherent conflict between the two and, indeed, that the two supported and were complementary to each other. The work of twenty years in the grandest files of medical times has not carried us far beyond that point. There is still as good a case for Metchnikoff as for Ehrlich; immunology is still (as a distinguished immunologist once said) "a science of *phenomena* not of *facts*."

The manner in which the subject matter of this volume is treated is symbolic of the author's own progress. The basis of the work is comparative zoology and comparative physiology. The simplicity and the clarity with which Metchnikoff recites the story of how his earliest observations on intracellular digestion—made when studying the comparative embryology and physiology of the digestive organs—led finally to the epoch-making contribution, phagocytic action and the theory of cellular immunity, are truly charming. Immunity reactions are set forth here as the

diverse reactions of all living things. The immunity responses of unicellular organisms (Chapter I) and of multicellular plants (Chapter II) are discussed before immunity in the animal kingdom (Chapter III). Then comes the treatment of the comparative physiology of "Resorption of the Formed Elements" (Chapter IV) and "Resorption of Albuminoid Fluids" (Chapter V). Then follow ten fascinating chapters on the facts and the mechanisms of natural and acquired immunity against microorganisms and their toxins. Chapter XVI is an historical sketch of our knowledge of immunity, and Chapter XVII a summary of the whole. The typography and make-up of the volume leave nothing to be desired. They are up to the highest standards of any press. The rhetoric and grammar of the original French edition have not suffered by the able translation of Professor Binnie.

It is not often that a volume on an experimental thesis bears the brunt of time as this one of Metchnikoff's. When reading it we smile sometimes for the many alleged facts or conceptions which have been denied or disproved since the opening of the twentieth century. We also smile—often, too—with wonderment at the predictions of discoveries yet to come and which in retrospect we know did come along the lines of investigation indicated by this able Russian. Indeed one is reminded of

a similarity to the fulfillment which came so hard upon the heels of another Russian's predictions, Mendeléeff's following the announcement of the periodic system of the elements. It was a long cry from studies upon *phagocytella* and intracellular digestion to the matured concepts of phagocytosis and artificial immunity. But Metchnikoff was a toiler and great was his perseverance. His book is an absorbing, interesting encyclopedia of information to the casual reader, a mine to the student of immune reactions, and an inspiration to all who thumb the pages.—I. S. FALK.

University Press, Cambridge, 1922.

## Clinical Tuberculosis

Rather a vast project was undertaken in "Clinical Tuberculosis," by F. M. Pottenger and the second edition of the two volume work brings up to date the material presented in the first. Much of the "new" of the second edition is based on personal observations, a vast clinical experience giving the author an unusual opportunity for testing out personal ideas. The discussion of the various reactions has been modified to conform to the views expressed by Pottenger in another book. The discussion is at times highly theoretical and difficult to follow. The book constitutes a valuable reference.

## New Cancer Research Laboratory

Keystone View Company, Inc.  
Huntington Memorial Hospital where cancer research work and optic wave study is being carried on. A new laboratory has been erected adjoining the hospital.

## The effect of the yeast treatment on uric acid excretion

*An interesting investigation of the effect of fresh yeast on uric acid excretion in normal persons has been recently conducted and reported upon. (See Journal of Laboratory and Clinical Medicine, May, 1922.)*

THE yeast cakes were eaten before meals by two men and two women subjects. One ate 3 cakes a day for ten days. Another ate 3 cakes for six days, then 6 cakes for four days; the third ate 3 cakes for three days, 6 cakes for three days and 9 cakes for four days; and the fourth ate 3 cakes for three days, 6 cakes for three days, 9 cakes for three days and 15 cakes for one day.

The daily diet was similar to the conventional "purine free" diet based on eggs, milk and cheese except that it was found desirable to include a vegetable salad in the noon meal. The same food was eaten every day. Approximately forty calories per kilo were provided and the weight of the subjects remained constant throughout.

The uric acid in the urine was determined by the colorimetric method of Folin and Wu. Hydrogen ion concentration was done by the colorimetric method using methyl red and thymol blue as indicators. Total nitrogen was determined by the Kjeldahl method.

The experiment was divided into four periods—a fore period when no yeast was eaten—a yeast period—and two after-

periods when no yeast was eaten. "There was no significant change in the values for uric acid in any of the subjects throughout the experiment," comments the scientist.

This result seems remarkable when one considers that for certain periods three of the subjects ate twice the therapeutic dose of yeast, two ate three times the dose and one ate five times the dose.

The summary states that "there is no evidence of an increase in uric acid excretion following the ingestion of the recommended therapeutic dose of live yeast."

The Fleischmann Company feel that this investigation proves conclusively that the ingestion of yeast does not increase uric acid excretion, and that, therefore, the advantages of yeast therapy are safely open to the nephritic and to those suffering from gout.

### *A New Authoritative Book*

Send for the recently published brochure on the manufacture, chemistry, physiology and therapy of yeast. This book is distributed free to physiological chemists, physicians and hospitals. Address THE FLEISCHMANN COMPANY, Dept. Y-8, 701 Washington St., New York City.

## Traveling Public Assured Safe Water

Travelers on ships which ply the Great Lakes will be protected against dangerous drinking water from now on under an extension of the national laws whereby the state department of health will cooperate with the United States Public Health Service in maintaining certified water on ships of the same standard as that now provided on railway trains.

Water used on lake vessels for drinking or cooking purposes, according to the regulations, must be obtained either on shore from a source approved by the United States Public Health Service and inspected regularly by the state department of health, or if not obtained ashore the water must be treated aboard ship by approved methods.

All water piping systems on ships will be required to be so arranged that no connections can be made between drinking water pipes and pipes for any other water system. Taps on ships yielding water not intended for drinking purposes will be marked by signs stating that the water is unfit to drink.

People may be assured that drinking water supplied on trains in Michigan is safe, declare officials of the State Department of Health, since rigid inspection is maintained of the 127 separate sources of supply for interstate carriers. A full time employee of the Bureau of Sanitary Engineering makes the inspections at stated intervals.

## Research Work in Ventilation

Tunnel ventilation in general and the Hudson tunnel ventilation in particular have developed an interesting body of facts in connection with underground air requirements states Robert G. Skerrett, writing for the *Compressed Air Magazine* of April, 1922. The difficulties in the way of blowing fresh air through the viaduct from end to end were overcome by a scheme which would introduce fresh air into each tube through a number of openings leading from a supply duct, and carry off the tainted air by another duct of like character. All the ventilation problems involved were cleared up by practical tests. The research work has just been finished, and supplies information of outstanding value in a number of fields of engineering.

Four lines of inquiry were followed, the first two having to do with the character and quantity of exhaust

gases generated by internal combustion engines when running and with the physiological effects of certain components of these gaseous mixtures—particularly carbon monoxid. The purposes of the latter research were to determine how human beings and animals would react when breathing for different intervals an atmosphere polluted with various proportions of carbon monoxid, and the point of safety in such admixtures for persons even of feeble constitutions. Another line of inquiry had to do with the evolution of a type of expansion chamber which would best serve to insure the widest dispersion of fresh air in the neighborhood of the tunnel roadways. Excessive velocities, of course, would need to be avoided. The accepted pattern is so shaped that air issuing from it at a velocity of one thousand feet per minute has no appreciable force five feet away, yet the impulse will carry the air quite to the middle of the driveway.

The road tests revealed the fact that the average volume of carbon monoxid produced is much larger than has previously been computed, a fundamental fact for the development of means to control its admixture with the air. The engineers had estimated that it

would not be unsafe for passengers in the tubes to breathe an atmosphere containing three parts of carbon monoxid in ten thousand parts of air, but the physiological experiments at Yale brought out the net result that men, women and children—including infants and invalids—could in perfect safety breathe for an hour an atmosphere admixed with four parts of carbon monoxid. Horses and dogs exhibited a like immunity.

Further experiments were conducted at the Experiment Station of the University of Illinois on the dispersion of air under the structural conditions involved, and at the experimental coal mine at Bruceton, Pa., to determine the relative advantages of delivering the fresh air supply from below. The difference was in favor of upward circulation, and the physiologists found that the absorption of carbon monoxid by the blood is less with the rising movement of air than with the descending movement.

The whole study emphasizes the comprehensiveness of studies involved in problems of ventilation, it shows the necessity of making human welfare a problem of engineering, and incidentally disproves many principles advocated by technical manuals.

## Convenient Iodin Container

A convenient iodine container for factories or large industrial establishments. The construction of a shelf just below the top of the bottles prevents the removal of the iodine and applicators from the box.

**“With this Treatment  
I Seldom Write a Death Certificate  
FOR  
INFANTILE DIARRHEA”**

*THE BRITISH MEDICAL JOURNAL SAYS:*

“All experience goes to show that Virol is a food of marked value in a great variety of conditions in which adequate nutrition by ordinary means is not easy to secure, including the general range of diseases accompanied by wasting and summer diarrhea.”

*“I have had most excellent results with Virol; in fact, to my mind it is the only treatment for infantile diarrhea—barley water and Virol, or rice water and Virol. With this treatment I seldom write a death certificate for infantile diarrhea.”*

Extract from doctor's letter.

## DIET IN INFANTILE DIARRHEA

To each half-pint of rice or barley water add one-quarter teaspoonful of Virol. Give one or two ounces of this mixture every two hours. In cases of great prostration add 10 to 15 minims of brandy. When the evacuations indicate that the infection is at an end, sterilized milk can be cautiously added to the Virolised rice or barley water, the milk being substituted for the rice or barley water, dram for dram, until Virolised milk is the sole article of diet. As the child improves the Virol can be gradually increased.

*A brochure on the treatment of acute summer diarrhea  
will be sent to any medical man on application.*

*Used in more than 2,500 hospitals and infant clinics in Great Britain.*

*Sole Agents for U. S. A.*

**GEO. C. COOK & CO., Inc., 59 Bank Street, New York**

## Incineration as Means of Garbage Disposal

Incinerators have been found to be an efficient as well as a comparatively inexpensive means of disposing of refuse for market houses and large industrial and institutional buildings. William F. Morse, consulting sanitary engineer of Cleveland in *Municipal and County Engineering* has described a simple type of incinerator in practical use.

Incineration is the most satisfactory method of disposing of market house wastes. With a market containing from 100 to 150 stalls, handling every variety of food products, there is a daily accumulation of refuse material of from 10 to 15 cubic yards, weighing approximately 3 to 5 tons.

The incinerator may be built from detailed working drawings by a competent bricklayer who can read plans and follow clearly printed instructions. Though the design may be varied to conform to the architect's plans, the floor space should not be less than 8 ft. by 6 ft. with room on the side or end for stoking and removing ashes. The incinerator is usually connected with the main chimney of the heating plant or with the boiler smoke flue; or if the location is outside the building, there is provided a brick chimney or steel stack with fire brick lining.

The fire-box, floored with heavy cast-iron grates, is charged from the main floor of the building through a chute covered by a fire-clay slab enclosed in a cast iron rotating frame. The interior walls, roof, and connecting flue are of fire brick and the whole construction is braced and stayed by vertical and horizontal steel beams and angles. The consuming heat may be raised to the highest temperature and maintained indefinitely without injury to the furnace. No fuel other than the refuse itself is required to operate the furnace.

Incinerators are also most successfully used at great railway terminals. In the Hudson Terminal Building, New York City, which has 5,000 daily occupants and a connecting underground railway, there is installed an incinerator designed and built by the author in 1907. The furnace with a capacity of ten tons receives the daily garbage, combustible refuse, floor sweepings, and the refuse from the railway used by thousands of travelers.

At the Bush Terminal Building, South Brooklyn, N. Y., the enormous volume of refuse from the industrial plants housed therein is transformed into steam by the aid of two large

incinerators which use no other fuel and operate two 350 h.p. steam boilers, saving an equivalent amount of coal.

The Government makes use of incinerators at various army posts and navy yards. One incinerator has been in use in a certain army post since 1894.

## Infant Mortality in New York City

A new emphasis has been placed upon the effectiveness of direct and intensive efforts in the reduction of the infant mortality rate through the publication of "Infant Mortality in New York City" by the International Health Board. The study is based upon data collected in 1915 and 1916 by Ernst Christopher Meyer. The text deals with the material in hand when the study was closed in 1916, but all important tables and graphs have been brought up-to-date.

No other city in the country has been able to show an equally rapid and constant decline in its infant mortality. What is likewise remarkable is the fact that a parallel reduction has taken place in the death rate among children from two to five years of age. That the results attained bear a direct relation to the activities undertaken in child welfare is evidenced graphically by the trend of the congenital disease rate, the movement by groups of diseases, the

relation of baby health stations to the decline in diarrheal diseases. Larger movements to include domestic sanitation and personal cleanliness, growing out of the special programs are held to attain the particularized goal of infant welfare, and at the same time to be quicker and more economical than the method of the past in a concentration at the outset on expensive, intensive infant care. A city with a very high infant mortality rate has generally very poor conditions of sanitation, and, in the end, anything less than community effort toward community betterment must be considered inadequate.

## Lunches in Tuberculosis Crusade

The Wisconsin Tuberculosis Society has been very active in the advocacy of nutritional work in schools as a prophylactic against tuberculosis. As a result of the hot lunch campaign completed recently in Dane county, many schools have installed equipment and will continue the lunches permanently. The campaign was conducted for two weeks in the 240 rural schools of the county under the direction of the county nurses and supervising teachers.

Milk lunches have been introduced into the Waupun schools as a result of the school inspection conducted by Miss Alma Witte, public health nurse.

## The Exhibitor's Problems

THE movie wins, whether it is deliberately sought out by a pleasure loving public for purposes of recreation, or whether the visual appeal is utilized by educator, scientist, or moralist as the most direct stimulus to action. Not a word of defense for the use of the screen is offered by Gladys and Henry Bollman in "Motion Pictures for Community Needs," for enterprise in that direction has sufficiently demonstrated its efficacy. It does, however, present the most comprehensive analysis of subjects having to do with production that must be mastered by the non-theatrical exhibitor if the motion picture film is to serve him, selection and booking, fields of utility, harmonious settings, program building, and hundreds of questions satisfactorily solved by experts in projection and management which can serve the ends of the community exhibitor.

A list of publications and bibliography (complete to publication date)

is presented along with one hundred suitable programs. Questions of equipment and installation, operation and care of films, legal regulations, and types of machines are set forth.

Perhaps the best service to the amateur exhibitor is given in the general analysis of the problem. The general suitability of a picture program depends upon the specific purpose it is to serve. Here as elsewhere success depends upon knowing exactly what is to be accomplished and sticking to it. This involves also an analysis of the audience. The supply of specially adapted pictures should govern their selection, as well as the status of the subject presented, and the temper of the public addressed. Haphazard methods no longer suffice. If visual appeal through motion pictures is to be made, all available service to make that appeal intelligent and intelligible should be utilized.

*In one small unit—*  
**Complete Sterilization**

**I** NSTRUMENT and Dressing Sterilizers are combined with Water Sterilizer in one compact service-giving outfit. It is a new unit, but has years of practical experience behind it. The money cost to you is exceedingly moderate.

It is the Castle No. 1512. Dressings are sterilized by "live" steam, instruments by boiling. The table top is heat and acid proof, and beneath is an aseptic cabinet for supplies. Illustration shows gas heat, but made also for other heats. Electric unit never can boil dry.

*CUT out this Castle ad. and send it to your dealer for further information. Or ask us directly any question you think of concerning your own particular sterilizing problem.*

**WILMOT CASTLE CO.**  
 1153 UNIVERSITY AVE., ROCHESTER, N. Y.

*Makers also of complete group of Pressure Sterilizers for Hospitals and Laboratories.*

## Problems in Delinquency

JUVENILE delinquency can be prevented and in the process a large part of adult criminality can be eradicated, asserts Goddard\* in "Juvenile Delinquency." Defining delinquency as failure to keep up the requirements of the group, social offenders fall into two large divisions, (1) the feeble-minded who cannot understand reasons for and hence do not develop motives for social behavior; and (2) the psychopathics, who, though they may be able to understand the nature and need of cooperative enterprise, are because of inherent defect unable to control their actions. Penal measures conducted on the principle of retribution, or custodial care, to get the troublesome individual out of the way, merely beg the question of the socially inadequate. If a social behavior is the result of physical or mental defect, the offender is as abnormal on the first offense as when he commits a serious crime. If treatment in such cases is justifiable to all, prevention is more justifiable, and this becomes possible only when the disposition of such cases is made only on the basis of exhaustive analytical study.

Ohio is in a fair way to solve the question through the Bureau of Juvenile Research. Organized in 1912 after a preliminary survey of problem children, the personnel of the Bureau included mental examiners and diagnosticians, psychiatrists to study mental disease, biochemists for the study of physiological processes, physicians for physical examination and treatment, and other specialists necessary to attack the complex problems that are involved in juvenile delinquency. The work has gradually been extended till in 1920-21 there were ten scientific workers, six clerks and stenographers, and nine caretakers.

On the medical side, while emphasis is placed upon complete treatment for remediable disease and physical defect, intelligent handling is held to depend chiefly upon mental classifications. In a large proportion of cases Goddard is inclined to attach chief importance to congenital syphilis as a causative factor, a condition identified with very typical effects upon conduct as well as mental function.

A statement of results, a summary of findings, and general indications for an effectual program for eradicating juvenile delinquency are outlined

in Goddard's book. It is a volume of real value to physicians and public health or social workers, but it would be still more effectual if a volume of this character could be accorded a careful reading on the part of the general public. For the questions it raises are social questions, problems which are still open because they are not understood and faced directly by the group concerned. For the most part the machinery to handle the question is locally available.

The chief opportunity for prevention is through the public schools. Waste of time and money is involved in a system which delegated the problem of the feeble-minded to state institutions at a time when it was thought that a small institution con-

veniently located would easily take care of all the mental defectives in the state. Social inadequacy is closely allied to mental defect and as such should receive attention in due course through specially adopted educational measures. The first business of our schools is to socialize the child. If they merely seek to impose a given amount of information instead of training him into modes of behavior that are socially adequate, they fail fundamentally to serve the state. It is logical, therefore, that the physically or psychically inadequate child shall be discovered early in his school career and, once discovered, that machinery to prevent delinquency will be applicable there to replace the cumbersome and ineffectual correctives which now are applied through juvenile courts and bureaus of juvenile research.

## Rural Child Welfare

OUR lethargic attitude toward the problems of child life has been brought squarely to our attention again. What sort of a society is it which can through its events of justice defeat justice and reason as we sometimes do with our cumbersome machinery? The endless thought and attention which the National Child Labor Committee has given to the problems of child life make their publications worthy of our most cordial consideration. A recent publication on Rural Child Welfare, a study of conditions in West Virginia made under the direction of Edward N. Clopper, shows us again and again how far we have to go before we accomplish even the minimum of existence.

The primary purpose of child welfare work, Mr. Clopper shows, is to prolong the period of childhood. Success for boys and girls depends first of all on the time element—the certainty of childhood. It is not enough merely to have childhood; it must be made secure to all sorts and kinds of children. Suffering and disease, poverty and crime, are not a part of wholesome child life. Above all, let them play, for play is the means to growth and refreshment. Protective, educative, recreational, and charitable work—on these we must rely to keep the canker of age out of childhood.

We have talked vaguely of the problems of rural life, the position of the child on the farms, and the char-

acter of his life but here we find a study of the rural home, its sanitation, the character of food, child labor, rural recreation, dependency, neglect, and delinquency among children. It might be shown for instance that of 183 schools visited 95 or over one half reported their non-attendance to no one. These figures and the cause of non-attendance have been carefully analyzed. Sometimes the children are excused for work, sometimes because of illness, sometimes because of the location of the school.

Probably the most basic of all causes of non-attendance is indifference. Indifference to education, and particularly education expressed in terms of school attendance, is very general and is manifested not only by parents and children but by the whole community, including school people themselves. This problem of indifference and inattention is probably the most fundamental of our difficulties—indifference to health, to child care, to all sorts and kinds of problems.

The following expenditures of various states in health work for rural inhabitants for the year 1920 bear out what we have said: South Carolina spends 16 cents per capita; Kentucky 15 cents; North Carolina, 13 cents; Virginia 10 cents; Mississippi, 9 cents; Alabama, 8 cents; Georgia, 8 cents; Tennessee, 5 cents; and West Virginia 5 cents.

# Heathization Improves A Good Product!

**H**EATHIZATION—the science of keeping air out of goods—is not a “cure-all” for poor materials. In fact, if a product lacked genuine quality and Heathization were used, this lack would be emphasized.

Heathization makes a good product better, cleaner, more delicious, more wholesome.

The fact that a certain brand of ice cream, butter or bread was Heathized would be, in itself, a proof of the quality of the product.

One of the first qualifications we demand of any manufacturer asking for a Heathizing license is that his product be good. It must be well made. It must be made in clean, sanitary surroundings.

So the more than 200 Heathizers are bound together by no other ties than the desire to give the public the best, the purest, the cleanest produce that money, brains and science can produce.

Keeping ordinary air out of foods is recognized as one of the century's most important advances in food sanitation. Everyone knows that air is a destructive agent to food stuffs.

There are many things you should know about Heathization. We will gladly furnish you interesting reprints of articles from medical publications telling how this endeavor for better, cleaner food has gained headway.

## FROM THE FIELD

Columbia University now has a School of Public Health established under the bequest of Joseph R. De Lamar of \$777,772.45. While the institute will be primarily for research and for the training of research workers, it will also offer instruction to students of medicine and to others, and will give publicity in popular form to results of scientific investigation in the whole field of public health and hygiene. Dr. Haven Emerson has been appointed Professor of Public Health and Administration.

The Civic Federation of Dallas, Texas, has conducted a study of constructive work for girls, based on replies from Boston, Chicago, Cincinnati, Cleveland, Columbus, Dayton, Fort Wayne, Kansas City, Milwaukee, Minneapolis, Sioux City, and Youngstown. The consensus of opinion seems to be that the best known organizations, the Camp Fire Girls, Girl Scouts, and Girl Reserves of the Y. W. C. A., as well as other organizations, are all doing successful work and fill a need.

"The Housing and Equipment of Kindergartens" is a condensed detailed study published by the Government Printing Office. It contains illustrations of the floor plans of the kindergarten at Wellesley college, views of the Francis W. Parker kindergarten of San Diego, Cal., and of the kindergarten in the State Normal School, Superior, Wis. Minimum and adequate lists for kindergartens of thirty children are published together with their costs.

A new publication which made its first appearance in May is the *Archives of Medical Hydrology*, the journal of the International Society of Medical Hydrology, published in London. Editorial secretaries are C. W. Buckley, M.D., Buxton, England, and Paul Ferreyrolles, M.D., La-Bourboule, France. Many of the articles are published in both French and English. Original articles have been contributed by Leonard Hill, Alois Strasser, R. Wybauw, and others.

National Cancer Week will be held from November 12 to 18.

The personnel of mine-rescue car No. 6 of the Bureau of Mines has recently given first aid training to employees of lead mines and smelters at Flat River, St. Francois, and Desloge, Mo. The crew of rescue car No. 7 has trained employees of the Barnsdall Zinc Company and the Chanute Spelter Company in the Joplin, Mo. district. Car No. 9 recently completed training in the Butte, Montana, district and proceeded to the Coeur d'Alene district of Idaho. First aid, mine rescue, and allied safety work has been done by car No. 10 on the Mesabi and Vermillion iron ranges of Minnesota. Jesse Henson, station foreman at the Wilkes-Barre, Pa., safety station of the Bureau of Mines, recently gave first aid training to employees of the New Jersey Zinc Company, Franklin, N. J.

The San Francisco Board of Health budget for the coming fiscal year has been submitted and totals \$4,000,000. This includes \$15,000 for radium, \$11,000 for a building to house women discharged from state institutions, \$1,500,000 for new buildings at the Relief Home, and \$500,000 for a new board of health building.

The object of a new investigation to be undertaken by the United States Bureau of Mines in the Minnesota iron range district is to study the physiological effects upon miners of underground conditions, such as high temperature, humidity, gas and dust, and to make physical examinations to obtain any evidence of miners' phthisis (silicosis) among the miners. F. V. Meriwether, surgeon, has been assigned to the investigation, which will probably consume the next six months.

The committee of the French Academy of Medicine, appointed by the Academy to make a study of the reform needed in the secondary education system of France, has made the following recommendations: Limitation of the daily amount of time to be spent in study, to eight hours; organization in high schools of games and manual training in addition to physical education proper; limitations of classes to 30 pupils and grading classes according to intelligence; lightening and simplifying the curri-

culum; extending the duties of the school physician to cover all matters relating to school hygiene; and the keeping of health records for each pupil.

The motorized child health center, known as the Child Welfare Special, recently built for the Wisconsin state board of health, toured Rock County in April and Grant county in May, giving physical examinations for infants and pre-school children. Other counties on this year's schedule are Sheboygan, Manitowoc, Oconto, Oneida, Bayfield, Portage, Monroe, and Juneau. The pediatric work is done by Dr. Blanche Horner-Rivers, formerly in similar work in Mississippi. Mrs. Johanna Clark, Fort Atkinson, Wis., is nurse assistant.

Carbon tetrachlorid, a cheap chemical commonly used as a clothes cleaner, seems to be a cure for hookworm in human beings, according to recent reports from the Fiji Islands and Ceylon covering thousands of cases showing practically 100 per cent successes. The discovery of the efficacy of the drug in removing these parasites was made by Dr. Maurice C. Hall of the United States Department of Agriculture. Twelve thousand natives of the Fiji Islands, according to a telegraphic report recently received in London, have been successfully treated by the same method, a single dose removing all these parasites from 90 per cent of the patients and at least 98 per cent of them from all persons treated. This is the most extensive test of the chemical yet made on human beings.

The Eleventh Annual Congress of the National Safety Council will be held in Detroit, Mich., August 28-September 1: Many special features of interest are added this year; noted experts in safety and related subjects will address the meetings; a safety exhibit will be held; new safety motion pictures will be shown. An opportunity will be afforded to visit the plant of the Ford Motor Company, employing 46,000 men and turning out 5,000 cars daily.

The Wisconsin Industrial Commission has ruled that tuberculosis acquired as a result of occupational duty is compensable under the "occupational disease amendment" enacted by the 1919 Legislature. The case was that of a "wet grinder" in a factory who inhaled dust and fine particles until tuberculosis developed.

# 4 MONTHS' RESULTS

A Springfield (Mass.) woman suffered from flat feet and bunions caused by wearing narrow-toed shoes. A local doctor advised her to wear

## GROUND GRIPPER WALKING SHOES

She did, and he kept careful diagrams of her feet from April 19th to July 10th. The above drawings are reproduced from his records. They speak for themselves.

"GROUND GRIPPERS" are the ORIGINAL muscle-developing health shoes for Men, Women and Children. They are universally recommended by physicians and surgeons. Instead of imprisoning arches and toes, they flex naturally with your feet in every part—at every step. Nerve pressure is relieved—stagnant circulation quickened—weak muscles strengthened—painful swellings reduced—deformed bones straightened. Feet are completely restored to normal shape, vigor and comfort. And these results are permanent.

"GROUND GRIPPERS" are imitated but never duplicated

The growing interest among industrial executives in literature concerning the conservation of vision is shown by the report of the National Committee for the Prevention of Blindness by the statement that more than 3,400 sets of industrial eye accident posters were distributed during the last year, and by the fact that the second edition of the Committee's Bulletin No. 12, a volume of 145 pages devoted entirely to eye hazards in industrial occupations, was exhausted before the close of the year. This bulletin containing reports of typical cases and recommendations for safe practice is now being revised for publication in the Fall.

The Health Service, New York County Chapter American Red Cross, has issued a report giving results of the physical and mental examinations of over 1,300 N. Y. school children. One thousand children of pre-school age were made fit to enter school at the instance of the Committee on Education of the Civic Club, and with the cooperation of the New York City Department of Health and Education, the New York State Association of Consulting Psychologists.

Lee K. Frankel of New York City sailed for Europe, June 20, as head of the executive committee of the American Jewish Relief Commission to visit Jewish centers in order to determine the best way in which the \$18,000,000 collected in this country may be spent.

The Harvard Medical Commission which instituted a five year course of study into the causes and treatment of infantile paralysis, recently made a report of progress. The commission has two thousand actual cases under its supervision and is at the present time treating more than a thousand. The fundamental fact established is that only 50 per cent of the infantile paralysis cases are accompanied by paralysis. The after treatment of the disease is based on "muscle training."

H. Gray, M.D., of Boston has an article in the May number of the *American Journal of Diseases of Children* dealing with the sitting-height and stem-length of private school boys. The children studied are of American birth, of pure American stock; they are drawn from a well nourished class. One hundred fourteen boys were studied.

*The Long Island Medical Journal* publishes an article by Harris Moak, M.D., Brooklyn, on "Raw Milk in Relation to Nutrition," being an account of the work in the milk commission of the Medical Society of the County of Kings. The requirements for certified milk are set forth in the paper.

"Office Administration for Organizations Supervising the Health of Mothers, Infants, and Children of Pre-school Age with Special Reference to Public Health Nursing Agencies," by Estelle B. Hunter, U. S. Children's Bureau Publication No. 101, embodies the experience of members of the bureau's staff whose services were loaned for studies and consultations, and the results of a study of methods used by 200 nursing agencies in both large and small communities. Among the subjects with which it deals are: The principles and methods of staff organization; selection and training of employees; office location and arrangement; selection of office furniture, equipment, and supplies; planning case record systems; filing, financial administration; and publicity methods. It includes a bibliography and an appendix giving details of four record systems in use by different types of nursing organizations.

*The Commonwealth*, published by the Massachusetts Department of Public Health, devotes its March-April issue to mental hygiene. It contains articles on various phases of the subject by Drs. Harry C. Solomon, Donald Gregg, Abraham Myerson, William Healy, D. A. Thom, A. Warren Stearns, and George K. Pratt. The issue also contains a list of health plays and the organizations from which they may be obtained.

A standard smoke ordinance to apply to all cities of the country will be framed by the engineering profession according to announcement of the American Society of Mechanical Engineers. The committee to carry on the work nationally consists of O. P. Hood, chief mechanical engineer of the United States Bureau of Mines as chairman, Henry Kreisinger, P. J. Dougherty, Lloyd R. Stowe, Everett L. Aillard, and Osborn Monnett.

Harrison G. Dyar, Custodian of Lepidoptera, United States National Museum, is the author of a bulletin "The Mosquitoes of the United States," published by the Government Printing Office, Washington.

The section on Pediatrics of the Associated Out-Patient Clinics which in 1914 adopted standards for Class A, B, and C clinics was reorganized on May 10, 1922, with the following officers: Chairman, Robert H. Dennett, M.D.; vice chairman, William P. St. Lawrence, M.D.; executive secretary, Gertrude E. Sturges, M.D.; executive committee: Murray Bass, M.D., Stafford McLean, M.D., Marshall C. Pease, Jr., M.D., Mark S. Reuben, M.D., Frank Howard Richardson, M.D., Louis C. Schroeder, M.D., Charles Hendee Smith, M.D., and the officers.

In a recent report presented to the Conseil Supérieur d'Hygiène Publique de France by a special committee on the subject of the use of white lead in industry, the investigators point out that the restrictions laid down by the International Labor Conference at Geneva fall short of the legislation already adopted in France. They urge that Article 79 of the French Labor Code be extended to include painting of all sorts of vehicles.

The Bureau of Children of the Pennsylvania Department of Public Health is making a study of the services rendered by various agencies to children, the information to be recorded and filed in Harrisburg. A representative state conference will be called to determine minimum standards upon the completion of the work. The staff is composed of trained workers in the various fields of child welfare.

One hundred thousand women and girls in New York City have banded together to launch a campaign to secure a center and clubhouse for wage-earning women. Mrs. Willard Straight is chairman of the committee of one hundred who will help raise the \$50,000. The clubhouse is to provide a meeting place for wives of working men. The plans of the new house, which is to be located somewhere between Twenty-third and Forty-second streets not further west than Seventh avenue, including an auditorium, rooms for committee meetings, classes, and union gatherings; a cafeteria, library, and other facilities.

In cooperation with the New York State Department of Health, New York University and Bellevue Hospital Medical College will give a correspondence course in public health nursing open to all registered nurses beginning September 5, 1922.

# Arhovin

No matter what your favorite local treatment in Gonorrhoea and its complications, you can render it more *promptly* and more *permanently* effective by supporting it with internal Arhovin medication.

For over fifteen years, Arhovin has successfully taken the place of santal oil and balsams in the practice of a host of specialists and general practitioners, because it does not irritate the stomach, or kidneys, nor impart a tell-tale odor to the breath.

Furnished in tins of fifty capsules, each 4 minims.

Dosage: One or two capsules, three to six times daily, after meals.

Information, Sample and Literature from

**Schering & Glatz, Inc.**  
150 Maiden Lane NEW YORK

## Nourishing Food

Vigorous, healthy children, made so by the use of Hemo, are a delight to all.

# HEMO

for girls and boys in school. A nourishing luncheon or an inviting between meal drink.

Hemo is well adapted for use wherever delicious, sustaining malted food drinks are desirable. SCHOOLS, COLLEGES, PUBLIC HEALTH and INDUSTRIAL WELFARE DEPARTMENTS, Y. M. C. A.'s, Y. W. C. A.'s, we invite your correspondence.

Sample sent free upon request.

The New York City Board of Health hopes to immunize from diphtheria every child in the city between the ages of six months and six years before the opening of the schools in the fall. The work has been begun under the direction of Dr. Abraham Zingher of the Willard Parker Hospital. Natural immunity will be determined by the Schick test and those who fail to pass will be inoculated with the toxin-antitoxin. A giant educational campaign is now being conducted in New York City in an effort to reach the parents of every child.

Osteopathy is to be tested at the Peter Bent Brigham Hospital, Boston, under the auspices of the Massachusetts Medical Society and the Harvard Medical School.

The Maternity Center Association of New York plans to distribute authoritative information on prenatal care among 100,000 mothers in the United States in an effort to save more than 200,000 lives.

The National Health Council, Washington, D. C., has issued a mimeographed report on the Bureau of Animal Industry setting forth the legal authority, history and development of the Bureau, its organization, personnel, appropriations, and cooperation with other agencies. The pamphlet is the eighth in a series issued by the Council. It is planned in the near future to combine all of these reports in a single printed pamphlet, thus offering for the first time correlated and accurate information concerning the public health work of the United States Government.

Oct. 16 to 21 has been decided upon as "Management Week" by the American Society of Mechanical Engineers to stimulate interest in solving the problem of management in industry. Meetings will be held by engineers in all sections of the country. The Society of Industrial Engineers of which Professor Joseph N. Roe, head of the Department of Industrial Engineering of New York University is president, and the Taylor Society will co-operate.

A life insurance corporation to furnish insurance at cost to clergymen and certain lay workers of the Protestant Episcopal Church is being formed by men prominent in the church, including Bishop William T. Manning, Bishop William Lawrence

of Massachusetts, and J. P. Morgan. The new corporation, the formation of which has been announced in legal advertisements, is to be known as the Church Life Insurance Corporation. It will be incorporated in New York state with a capital of \$150,000.

The insurance plan is a development of the work of the Church Pension Fund, organized in 1917 to provide pensions for retired and disabled clergymen and their families. The fund has \$14,000,000 in hand and \$10,000,000 more promised. The insurance plan is an addition to the pension system and not a substitute for it. The Church Pension Fund will provide temporarily the \$150,000 capital of the insurance corporation.

That federal protection must be restored to American children through amendment to the Constitution and the passage by Congress of another child labor law and that any further attempts to secure federal legislation without a constitutional amendment would be folly now that the U. S. Supreme Court has successively found two federal child labor laws invalid on constitutional grounds was the statement of Owen R. Lovejoy before the Seventeenth National Conference on Child Labor held in Providence, June 27.

Invitations to send delegates to the World's Dairy Congress, to be held in the Fall of 1923, have just been sent by the United States to the Governments of about fifty countries. The United States Department of Agriculture is cooperating with the World's Dairy Congress Association and many department men are doing active work on committees in making preparations. The place of meeting has not yet been selected. Eminent authorities from all parts of the world will take part in the program, which is designed to touch on every phase of the industry from production to consumption that will be of interest to the people of many countries.

Dr. Alec N. Thomson has recently joined the staff of the Committee on Dispensary Development of the United Hospital Fund. Dr. Thomson was chiefly responsible for the organization of the urological pay clinic in the Brooklyn Hospital in 1914 and served with Colonel William F. Snow in venereal disease control both in this country and abroad. He still retains his connection as advising member of the department of medical activities; American Social Hygiene Association.

The need for physical training for young people is at present being widely discussed in Germany. A bill has been proposed requiring public and private athletic societies to organize sports for boys and girls and to make participation in them compulsory. Supervision of sports by state physicians has been suggested. Health centers for examinations and consultations to promote hygiene in sports have been established by private effort in Berlin, Hanover, and Hamburg, and centers in other cities are soon to be opened.

The Metropolitan Life Insurance Company is issuing to its industrial policy holders a layette pattern designed by Dr. S. Josephine Baker, Director of the Bureau of Child Hygiene, New York City Department of Health. The patterns are unique in that all the garments open all the way down the front. The measurements are such that the clothes can be worn by the baby for a year. A limited number are being distributed to child welfare and maternity centers.

The Water Works Manufacturing Association has elected the following officers: President, Edgar J. Bittenheim, *The American City*; vice-president, Charles R. Wood, R. D. Wood & Company, Philadelphia; secretary, John A. Kienle, Mathieson Alkali Works, Inc., New York City; treasurer, Dennis O'Brien, A. P. Smith Manufacturing Company, East Orange, N. J.

The story of Pennsylvania's Bureau of Municipalities in the State Department of Internal Affairs and the aid it gives to cities is told in *The American City* by James F. Woodward, Secretary of Internal Affairs of Pennsylvania. The bureau maintains a trained corps of municipal experts to extend free aid to the municipalities within its boundaries. The help consists of furnishing plans for playgrounds, widening streets, etc., as well as statistics dealing with fire, police, water departments, appropriations for parks, sewerage systems, street paving and garbage.

New Haven industries are being visited by high school boys to inform themselves as to a choice of a vocation. In order to facilitate the trips, the Chamber of Commerce has sent a questionnaire to each of the industries asking that talks be given explaining the industry.

**CHILDREN'S  
SHOES**  
that are  
*Scientifically  
Designed*

MANY physicians and nurses are accustomed to prescribe Health Maker Shoes for children, because of the scientific care with which they are designed. Each Health Maker Shoe is built to follow the natural foot contour, to give support where needed, to allow ample toe space, to provide for the proper development of the child's foot at every stage.

The inherent quality in Health Maker Shoes insures long service; the sensible lasts provide for natural and healthful foot growth.

***Certainty of Quality  
Promptness of Service***

There is frequently an urgency in the requirements of a Public Health Department, Dispensary, Industrial Hospitals and Surgeons in charge of the health groups, that calls for more than ordinary cooperation on the part of the supply house. Likewise there must be a positive assurance of the quality of each and every item.

With a full appreciation of these conditions the Chemists Supply Co. seek the patronage of these groups. Intelligent service is given on every order; the quality of our product satisfies the most exacting. The various chemicals, vaccines, solutions in ampoules, drug specialties and kindred supplies used daily or in an emergency, are at all times available. in necessary quantities.

*Try us in an emergency—Your satisfaction  
will assure your routine business.*

## The Disposal of Human Waste

Polluted streams and stinking hill slopes infested with rats and dipterous larvae are more than a political crime, states *The Lancet* in discussing two experiments designed to solve the problem connected with the loss of nitrogen which should be returned to the soil, but which constitutes waste in our present methods of disposing of human rejections. A local enterprise in the nature of biological husbandry has been undertaken at Sheffield, England.

The first of two experiments concerns the rapid disposal of mixed sewage so as to retain its fertilizing value in concentrated solid form, while the effluent is discharged clear and bright into the small river whose name is known only in the locality. Anaerobic processes by which mixed sewage is rapidly liquefied in so-called septic tanks have been found impossible and purification has been undertaken by mechanically increasing the oxygen content of the sewage, compressed air being brought to bear on a mixture of sewage and bacterial sludge by means of perforated pipes and porous diffusers. The original experiments at Manchester proved this to be possible, and at Sheffield the process has been simplified by doing away with the compressed air machinery and aerating the sludge by means of churning with paddles.

A concrete canal four feet wide, four feet deep, and three-fourths of a mile wide contains the bacterial sludge kept in a state of continuous circulation at the rate of about one and one-half feet per second by eighteen paddle wheels. In order to save space and make it possible for all the paddles to be driven by one engine, the canal is wound back and forth on itself, the double curves serving to produce eddies which conduce still further to aeration and complete mixture. When first put into use the canal contains just water, plus sufficient bacterial sludge—some 30 per cent of the total volume—collected from the existing filter beds of the older system. When the sludge has matured—that is to say, when the proper bacterial flora has developed—raw sewage is let into the canal at one point and mixes with the sludge during its three-quarter mile lap, the excess continually escaping over a wire situated just before the lap is completed, and in a wider part of the canal, where the flow being slower, the sludge has partly settled to the bottom. This overflow is then allowed to deposit the flocculent sludge completely in settling tanks and can then be immediately discharged into the river. The effluent is sparkling and gives ocular evidence of purity by the green algae which line the channel. Sufficient sludge is pumped back from the settling tank

to replenish the circulating system, the remained flowing away into a well where it can be dried and distributed at leisure. The sludge is quite inoffensive, the whole installation having less odor than a duck pond, and the process is continuous, year in and year out. One unit deals with a half million gallons of sewage daily in dry weather, increasing to over a million gallons in wet periods, for a population of 22,000, and Sheffield is now converting the rest of its disposal works, expecting to save in running expenses, to set free for other purposes five-sixths of its present filtered system, to obtain the market value for every part per cent of nitrogen in the dried sludge, and, last, but not least, to purge its hygienic conscience. A city starting its sewage disposal on these lines may do so at half the capital cost of the older system.

House refuse has hitherto been disposed of in Sheffield as elsewhere by dumping and incineration, and now the third alternative of salvage has passed the experimental stage. It has been fully demonstrated that salvage can replace indiscriminate destruction without harm to the health of the workers and without destroying the amenities of the neighborhood. Public health is well served by such demonstrations.

## Alter Public Health Curricula

As a result of the first investigation of all examining bodies granting degrees or diplomas in public health in Great Britain and Ireland for something like twenty-seven years, Dr. R. Bruce Low reports on the conditions found and on the recommendations of the General Medical Council

for systematic instruction and examination in a number of fresh subjects not formerly included in the curriculum, such, for instance, as the administrative control of tuberculosis, venereal diseases, maternity and child welfare, medical inspection of school children, medical entomology and parasitology.

The *Lancet* gives the details of the proposed alterations as follows:

There would be required for Part I, 180 hours in bacteriology (150 in practical laboratory work), and ninety hours in chemistry and physics (70 in the laboratory). Parasitology and entomology would be specifically included with bacteriology. For Part II there would be demanded three months' attendance at a fever hospital, with thirty attendances not less than twice a week; and six months' practical work (which could not be reduced) with a M.O.H. on at least sixty days of three hours each, the instruction to include maternity and child welfare, school medical service, venereal disease service, tuberculosis service, industrial hygiene, and the inspection and control of meat, milk, and other food. There would also be required instruction from approved teachers extending over not less than one hundred hours in the principles of public health and sanitation (30), epidemiology (20), sanitary law and administration (20), sanitary construction and planning (12), vital statistics (10), and meteorology and climatology (8).

## Massachusetts Poor Relief

Those who are active in the fields of charitable relief often forget the struggles which have preceded the laws of the movement. They are so engrossed in the immediate problem of relief that they have neither time nor effort to give to a study or survey of that which has preceded and that which follows. It is only by intensive study of what has been and what will be that we can effectuate our efforts.

Robert W. Kelso's "History of Public Poor Relief in Massachusetts" from 1620-1920 covers three hundred years of almsgiving showing defects and advances, progress and delays. We cannot here trace the rise of a consciousness on the part of society, of a responsibility towards its dependent groups, the development of a system operating in Massachusetts which decentralizes the administration of public poor relief by leaving it to the

smallest unit of government, the town, but which centralizes the development of general policy—the social program—in the State government.

As Kelso points out, this system as it now stands is essentially remedial and not preventive; it follows after the fact of developing but does not forestall its development. Public relief which seeks only to relieve distress ends by creating pauperism. If pauperism is due in the greatest measure to the lack of mental capacity in the individual to support himself and his dependents, to relieve him may be to perpetuate and propagate the same thing. Kelso concludes:

Under any form of government the utmost to be expected of the individual in the long run is self-interest decently pursued. Let this self-interest be taken for granted and self-support required by all means within the power of the normal citizen.

# Stanolind Petrolatum

*A Highly Refined Product of  
Absolute Purity—Superior In  
Color To Any Other Petrolatum*

“Superla White” is pure, pearly white, all pigmentation being removed by thorough and repeated filtering. Does not contain nor require white wax to maintain its color.

“Ivory white,” not so white as Superla, but compares favorably with grades usually sold as white petrolatum.

“Onyx,” well suited as a base for white ointments, where absolute purity of color is not necessary. Compares favorably with commercial cream petrolatum.

“Topaz” (a clear topaz bronze) has no counterpart—lighter than amber—darker than cream.

“Amber” compares in color with the commercial grades sold as extra amber—somewhat lighter than the ordinary petrolatums put up under this grade name.

*Standard Oil Company of Indiana guarantees  
the purity of Stanolind Petrolatum in all grades*

**Standard Oil Company**

*(Indiana)*

*Manufacturers of Medicinal Products from Petrolatum*

910 S. Michigan Ave. Chicago, U. S. A.

## The Play Movement in the United States

We think of recreation and play in a rather loose and undefined sense until we stop to consider its social significance and importance. Dr. C. E. Bainwater has recently published a report on "The Play Movement in the United States" in which the term "Play" is defined and the historical development of the movement for organized play traced. Play is used here as a "mode of human behavior, either individual or collective, involving pleasurable activity of any kind not undertaken for the sake of a reward beyond itself and performed during any age period of the individual, the particular action being determined at a given time by the somatic structure and social attitudes of the agent in conjunction with the life of the group or groups of which he is a member."

Until the last half of the Nineteenth Century the children of the United States possessed a richer play tradition than that of any other civilized country, but the lax attitude of the public toward child play, the rapid urbanization, the influx of foreigners and the increased isolation of rural communities had a distinct tendency to break down our inheritance of play in child as well as adult life. The creation of American folk music, folk dances, and folk games ceased with the decline of village and social life. Husking bees, spelling matches, and singing schools in which everyone participated were abandoned, leisure pursuits became commercialized, and participants were transformed into spectators. We see the first realization of the importance of new participation in recreational activities in the presence of sand gardens for children, then the introduction of gymnasiums, model playgrounds, small parks, recreational centers, civic art

and welfare, which finally broadened into the community center as a medium through which the members of the community get together and truly become members of the community welfare, prosperity and stability.

From the survey of developments which Dr. Rainwater has made it is evident that provision for play is not only an urban but a rural and national problem occasioned by social maladjustments arising from various causes and culminating in attempts to make adjustments to the social situation everywhere. It has started with provision for children and has spread to include adults and from philanthropic to community support, but there was little if any interest on the part of the majority of people in providing facilities for play. The enactment of state mandatory legislation opened the way for a new concept as shown in the general revival of festivals where folk dances and open air performances with hundreds of participants. The aim of the festivals should be to involve the people in self-amusement and self-expression. The festival should be the greatest and most characteristic form of democratic art. It should interpret the ideals of the people to themselves. It should stimulate the creative energies of the people, and bring forth the latent imagination and poetry which is in them.

The supervision of street play is an interesting development. In the earlier stages of the play interest, the attempt was made to keep the children off the street. The attempt now is that the play of children and adults on certain streets in congested areas is directed and organized when other facilities are lacking or are too few. Special games and activities have been adapted to the so-called play zone. The provision of camps outside the city limits under municipal control and support has developed to a place where they may be open

most of the year. Finally, we find the attempt to define standards, to bring about the social utilization of all leisure through the provision of opportunities for participation by all ages of people in behavior that is both personally developmental and socially constructive.

## Couch's Dictionary of Chemical Terms

The "Dictionary of Chemical Terms" by James F. Couch, chemist, Bureau of Animal Industry, United States Department of Agriculture, will be found very useful to chemists and other students of natural sciences. The definitions are clear, concise, and up to date.

D. Van Nostrand Company, New York, 1920.

## Park Health Moving Pictures

The parks of Detroit are carrying under the guise of a summer recreational activity a health educational enterprise of moment. By the time the summer is over every park in the city will be visited by three moving picture films on health subjects supplied by the Detroit Tuberculosis Society. By means of an automobile carrying a moving picture machine operated from the generator of the car it has been possible to present "Jinks," an animated cartoon on health, "Swat the Fly," a fly film, and "The White Bottle," a nutrition film showing the value of milk. It is believed that in this way a great many people will be reached with health instruction who could not be reached in any other way. The parks are thronged at night with people seeking fresh air and coolness. In the above way, the health instruction will be brought to them in an interesting form and the importance of individual cooperation emphasized.

## INDUSTRIAL SURGEONS

Yesterday industrial medical work was thought to belong to the young graduate without experience,—a bread-and-butter job, until a private practice was gained.

Today both the industrial executive and the physician and surgeon recognize that intensive training and specialized experience are necessary.

Aznoe's Service, likewise recognizes these conditions and seeks, by discriminating selection to serve intelligently both the industry and the surgeon.

At the present time many thoroughly qualified industrial surgeons are available for this specialized practice.

*Let us tell you how Aznoe serves both the industry and the individual.*

Central Registry  
for Nurses

30 N. Michigan Ave., Chicago

**DR. MOODY'S SANITARIUM San Antonio, Texas**

Established 1903. Strictly Ethical. For Nervous and Mental Diseases, Drug and Alcohol Addictions.

Modern clinical laboratory. Approved Diagnostic and Therapeutic methods. Bath room en suite. Steam heat, electric lights. Seven buildings, each with separate lawns, affording such scientific classification, both in-doors and out-doors, as is most conducive to genial, homelike environments, undisturbed rest and recreation, tactful nursing and individualized treatment, 100 rooms, large galleries, 15 acres of grounds, 350 shade trees, cement walks, play grounds. Location delightful summer and winter. T. L. Moody, M.D., Superintendent and Resident Physician. J. A. McIntosh, M. D., Resident Physician. Mrs. G. Lee, Matron.

**NEURONHURST**

DR. W. B. FLETCHER'S

**Sanatorium for Mental and Nervous Diseases**

A strictly Psychopathic Hospital. All forms of diseases arising from Organic or Functional Derangements of the Brain and Spinal Cord are treated. Special attention to Mental Cases requiring gynecological treatment. New building with capacity for fifty patients. Our Electro and Hydrotherapeutic advantages are unexcelled. Physicians desiring to place their patients in our care will receive every ethical attention. For further particulars and terms address Dr. Mary A. Spink, Superintendent

## Psychoanalysis and the Drama

A thesis, valuable either as a literary analysis of several current plays or as an exposition of certain hidden processes of the mind underlying human conduct and pointing the way to a satisfactory resolution through play-going, is brought out by Smith Ely Jelliffe, M.D., and Louise Brink, A.B., in "Psychoanalysis and the Drama." The dramatic power of the play lies in its conflict of psychic forces. Underlying motives are worked out to their logical conclusion, and because the tragedies of the drama are those of actual life, they afford a better acquaintance with and a safe outlet for the vast emotional life, the suppression of which so often causes mental and physical disaster in everyday life. Unsocial, unproductive forms of behavior are witnessed, acknowledged and thereby in the subjects themselves made subject to control. The functions of the drama are not merely recreational, nor even cultural and its survival through the centuries does not lie merely in the fact that it affords amusement and recreation.

Dramas presented upon the stage in recent years are analyzed as embodying given psychological denonement in chapters on: "Magic" and the Uncon-

scious; Visions of the Future; Phantasy Compensation Through Dreams; The Meeting of the Extremes; Compulsion and Freedom; The National Path of Sublimation; The Healing Function of the Dream; The Destruction Wrought Through Hate. Whether the drama is to be utilized as a therapeutic remedy by physicians or as a means of self-examination by the public, the book is recommended as interesting reading.

Nervous and Mental Disease Publishing Company, New York, 1922.

## Principles of Personnel Administration

The problem of securing and maintaining an effective personnel is one which confronts any executive. The personnel problems of the Federal and public service present many factors technical in character, not merely the selection of general principles but in determining the character of the organization and procedure which will put these principles into execution, the tests to be used in selecting new employees, their classification as to efficiency, etc. Arthur W. Proctor in his "Principles of Public Personnel Administration" published as one of a series covering the principles of ad-

ministration of the Institute for Government Research, has undertaken to trace and develop this new topic for discussion. The author briefly describes existing conditions and remedial measures are proposed. The discussion is limited to employment as it is carried on by civil service commissions in the national government and local governments.

D. Appleton & Co., New York, 1921.

## English Public Health

In this day of over-production of medical books in general, and of books on Infant Welfare in particular, it is refreshing to find a book that actually fills a gap in the literature. Such a work is the "Story of English Public Health," by Sir Malcolm Morris. It gives a historical resumé of the subject of public health in England and calls attention to problems that have as yet not been solved. It is too bad the author limited his work to English public health. There is a distinct need in medical literature for a book on the development of public health in general, and a comparative study on the future needs of public health in various countries.

## Rebuilding the Man

You are frequently consulted by men who have shot their physical and mental bolt. You may recommend a change and rest. A change, to be most beneficial, must be complete.

## Brown's Physical Training Farm

Affords just the change. A 300-acre farm upon the bluffs opposite and overlooking West Point assures a high elevation with a restful scenic view.

Fresh vegetables, fruits and other produce from the farm, and milk from a herd of registered tuberculin-tested Jersey cattle, bountifully supply the table.

A well-equipped Gymnasium, with steam baths, tennis courts, hand ball courts, horseback riding, swimming and golf are all a part of the regimen.

A Manor House offers accommodations in individual rooms. The training and physical upbuilding is under my personal supervision.

*Send for booklet, "Rebuilding the Man."*

## Food and Its Relation to Bodily Health\*

BY H. C. SHERMAN, PROFESSOR OF FOOD CHEMISTRY, COLUMBIA UNIVERSITY, NEW YORK CITY.

FIFTEEN or twenty years ago a paper on the subject of food and health would almost certainly have dealt chiefly with questions relating to disease. Students of health were then interested in food largely as a possible carrier of infection or deleterious substances either added as adulterants or produced by deterioration of the foodstuffs. The Federal Food and Drugs Act, in which for the first time the general pure food problem was attacked on broad lines and on a national scale, became a law sixteen years ago. In many states and cities, as for instance in Providence, under the able and scholarly leadership of Dr. Charles V. Chapin, excellent work in the sanitation of the food supply had already been started under local laws and ordinances. With the passage and enforcement of the Federal Food Law, such work became nation-wide, and effective coordination of the activities of state and city health officials and food inspectors was greatly facilitated and became much more broadly effective.

Not only is the general food supply now efficiently policed from the sanitary standpoint, but to an even greater extent has the general safety of the food supply been enhanced by the application of sanitary science in and by the food industries, largely under the constructive guidance of the United States Department of Agriculture and the state agricultural colleges and experiment stations on the one hand and the health authori-

ties of our states and cities on the other. So effectively has the science of sanitation been applied in the production, handling, and inspection of food in recent years that in general the consumer and social worker may now safely assume that food products offered for sale will not contain anything directly deleterious to health.

At the same time that the development of the science of sanitation and food legislation and inspection have largely relieved us from anxiety as to the safety of our food supply, the growth of our knowledge of nutrition has made it quite plain that a freely chosen food supply, adequate both to please the palate and to satisfy hunger, does not always meet all nutritive requirements so as to insure the full measure of health which each of us ought to enjoy. Thus the center of gravity of the problem of the relation of food to health has shifted from sanitation to nutrition.

We are now in a much better position to discuss the relation of food to health from the standpoint of nutrition than we were even a few years ago. Until recently we were hampered by the embarrassing fact that all attempts to nourish animals upon mixtures of carefully purified substances, containing all the chemical compounds then known as essential constituents of food, had ended in failure. Whether the nutritive failures resulting in such cases were due to faulty selection or combination of the nutrients entering into the artificial food mixture, or to the need of other substances in addition to those

known as essential, remained obscure until about ten years ago, when the work of Hopkins in England and of Osborne and Mendel and McCollum and Davis in this country made it clear that an adequate food supply must furnish certain substances which are absolutely essential, but whose existence was previously unknown, and which we now know as the vitamins.

Although the vitamins have not yet been isolated in chemically pure form, nor their exact chemical nature determined, yet we know enough of their occurrence in foods and their functions in nutrition so that we can include them in our consideration of food values and nutritive requirements. We can now state nutritive requirements in terms of the substances occurring in foods with confidence that we are taking account of all essential factors.

Such a statement requires the use of a few terms which might formerly have been regarded as technical but which have become household words through war-time discussions of food values and food conservation. From this point of view an adequate food supply may be described as one which furnished: (1) sufficient amounts of digestible material to yield when burned in the body the necessary number of calories of energy; (2) enough protein of suitable sorts; (3) adequate amounts and suitable proportions of mineral and inorganic elements (the "ash constituents" of the food); and (4) enough of at least three kinds of vitamins. All four of

\*Read before the Forty-ninth Annual Meeting of the National Conference of Social Work, Providence, R. I., June 22-29, 1922.

these requirements must be met by any food supply which is to be permanently adequate.

It was formerly common to illustrate the relation of food to bodily needs by likening the body to a steam engine. Somewhat better may the body and its food needs be compared to a gasoline engine and its requirements. The digestible organic food-stuffs such as fats, sugars and starches, correspond to the fuel for the engine; the proteins and some of the mineral matters to the materials of which the motor is made; other mineral matters to the lubricant; and the vitamins to the ignition sparks whose own energy is insignificant, but without which the engine cannot run, however fine the material of which it is built or however abundant and appropriate the supplies of fuel and of lubricant.

In practical problems of food supply we shall, of course, be dealing not with individual chemical constituents of foods but with articles of food as we meet them in the market. A brief statement of the outstanding nutritional characteristics of the chief articles or types of food may therefore be helpful at this point. The chief types of foods may be grouped according to their nutritive characters from the standpoint of our present knowledge of food values as follows:

(1) *Breadstuffs and other grain products*.—Economical sources of energy and protein, but not satisfactory in their mineral and vitamin content.

(2) *Sugars and fats*.—Chiefly important from the nutritional standpoint as supplementary sources of energy, although some fats are also important as sources of the fat-soluble vitamin.

(3) *Meats* (including fish and poultry).—Rich in protein or fat or both, but showing, in general, the same mineral and vitamin deficiencies as do the grains.

(4) *Fruits and vegetables*.—Greatly variable in their protein and energy values, but very important as sources of mineral elements and vitamins.

(5) *Milk*.—Important as source of energy, protein, mineral elements, and vitamins. The most efficient of all foods in making good the deficiencies of grains and in insuring the all-round adequacy of the diet.

It thus becomes apparent why a dietary made up, as so many American dietaries are, too largely of breadstuffs, meats, sweets and fats, may be satisfying to the palate and

to the traditional demand for variety, may furnish ample quota of protein and calories, with fats in any desired proportions, and yet may be inadequate because of faults in its mineral and vitamin content. We now understand how it is that fruits, vegetables and especially milk in its various forms, serve (in ways which until recently could not be fully understood and appreciated) to make good the deficiencies of breadstuffs, meats, sweets and most fats.

So rapid and interesting has been the development of what is often called the newer knowledge of nutrition that many appear to have been misled into supposing that it has supplanted or is trying to supplant the conceptions of nutrition which were current a decade ago. At the risk of repeating the obvious, I believe we should constantly insist that the newer knowledge of nutrition does not supplant but does supplement our former views. All that we have ever known about protein and calories is as important as it ever was, and we have learned to appreciate the importance of the mineral elements and vitamins also. Each of these four factors should be given due emphasis without overshadowing any of the others. Calories, protein, mineral elements, and vitamins all are equally important in the sense that each of these four factors or groups of factors is absolutely essential and must be properly provided in order that the food supply may be adequate.

In order to make proper application of our present knowledge of nutrition every food supply should contain such proportions of fruit and vegetables and of milk, along with other foods which may be cheaper sources of calories, that the eating of enough food to satisfy the appetite and the need for calories shall at the same time meet all the other needs as well. If we could make our present knowledge of food values and of the ways in which different foods supplement each other so clear and convincing that everyone would follow it in the choice and use of food, this would certainly mark one of the greatest advances in the application of knowledge to human welfare. For good nutrition is an even larger factor in health, happiness and efficiency than we have hitherto realized, and our present knowledge of food and nutrition guides us not only in so planning a food supply as to make it adequate in all respects, but also in showing how a food supply which is already adequate may be made still

better so that it will support a higher degree of health.

The Century dictionary defines health as: "Soundness of body; that condition of a living organism and of its various parts and functions which conduces to efficient and prolonged life. . . . Health implies, also, physiologically, the ability to produce offspring fitted to live long and perform efficiently the ordinary functions of their species."

We are somewhat accustomed to quantitative ratings of soundness and efficiency, and much more so to data of growth rates, birth rates, and statistics of duration of life. In human experience so many factors may enter to influence health in the course of a life time that it is hard to separate and measure the effects of food alone. But this can be done with laboratory animals of rapid growth and early maturity like the rat, and in experiments with the rat it is possible to determine under conditions uniform in all other respects the influence of food upon the various factors of health comprised in the definition just quoted.
